
The Python Library Reference

Release 2.7.16

**Guido van Rossum
and the Python development team**

July 09, 2019

**Python Software Foundation
Email: docs@python.org**

CONTENTS

| | | |
|----------|--|------------|
| 1 | Introduction | 3 |
| 2 | Built-in Functions | 5 |
| 3 | Non-essential Built-in Functions | 27 |
| 4 | Built-in Constants | 29 |
| 4.1 | Constants added by the <code>site</code> module | 29 |
| 5 | Built-in Types | 31 |
| 5.1 | Truth Value Testing | 31 |
| 5.2 | Boolean Operations — <code>and</code> , <code>or</code> , <code>not</code> | 31 |
| 5.3 | Comparisons | 32 |
| 5.4 | Numeric Types — <code>int</code> , <code>float</code> , <code>long</code> , <code>complex</code> | 33 |
| 5.5 | Iterator Types | 36 |
| 5.6 | Sequence Types — <code>str</code> , <code>unicode</code> , <code>list</code> , <code>tuple</code> , <code>bytearray</code> , <code>buffer</code> , <code>xrange</code> | 37 |
| 5.7 | Set Types — <code>set</code> , <code>frozenset</code> | 48 |
| 5.8 | Mapping Types — <code>dict</code> | 51 |
| 5.9 | File Objects | 56 |
| 5.10 | <code>memoryview</code> type | 59 |
| 5.11 | Context Manager Types | 61 |
| 5.12 | Other Built-in Types | 62 |
| 5.13 | Special Attributes | 64 |
| 6 | Built-in Exceptions | 65 |
| 6.1 | Exception hierarchy | 70 |
| 7 | String Services | 73 |
| 7.1 | <code>string</code> — Common string operations | 73 |
| 7.2 | <code>re</code> — Regular expression operations | 86 |
| 7.3 | <code>struct</code> — Interpret strings as packed binary data | 102 |
| 7.4 | <code>difflib</code> — Helpers for computing deltas | 107 |
| 7.5 | <code>StringIO</code> — Read and write strings as files | 117 |
| 7.6 | <code>cStringIO</code> — Faster version of <code>StringIO</code> | 117 |
| 7.7 | <code>textwrap</code> — Text wrapping and filling | 118 |
| 7.8 | <code>codecs</code> — Codec registry and base classes | 121 |
| 7.9 | <code>unicodedata</code> — Unicode Database | 135 |
| 7.10 | <code>stringprep</code> — Internet String Preparation | 137 |
| 7.11 | <code>fpformat</code> — Floating point conversions | 138 |
| 8 | Data Types | 141 |

| | | |
|-----------|--|------------|
| 8.1 | <code>datetime</code> — Basic date and time types | 141 |
| 8.2 | <code>calendar</code> — General calendar-related functions | 165 |
| 8.3 | <code>collections</code> — High-performance container datatypes | 169 |
| 8.4 | <code>heapq</code> — Heap queue algorithm | 184 |
| 8.5 | <code>bisect</code> — Array bisection algorithm | 187 |
| 8.6 | <code>array</code> — Efficient arrays of numeric values | 190 |
| 8.7 | <code>sets</code> — Unordered collections of unique elements | 192 |
| 8.8 | <code>sched</code> — Event scheduler | 196 |
| 8.9 | <code>mutex</code> — Mutual exclusion support | 197 |
| 8.10 | <code>Queue</code> — A synchronized queue class | 198 |
| 8.11 | <code>weakref</code> — Weak references | 200 |
| 8.12 | <code>UserDict</code> — Class wrapper for dictionary objects | 205 |
| 8.13 | <code>UserList</code> — Class wrapper for list objects | 206 |
| 8.14 | <code>UserString</code> — Class wrapper for string objects | 206 |
| 8.15 | <code>types</code> — Names for built-in types | 207 |
| 8.16 | <code>new</code> — Creation of runtime internal objects | 210 |
| 8.17 | <code>copy</code> — Shallow and deep copy operations | 210 |
| 8.18 | <code>pprint</code> — Data pretty printer | 211 |
| 8.19 | <code>repr</code> — Alternate <code>repr()</code> implementation | 214 |
| 9 | Numeric and Mathematical Modules | 217 |
| 9.1 | <code>numbers</code> — Numeric abstract base classes | 217 |
| 9.2 | <code>math</code> — Mathematical functions | 220 |
| 9.3 | <code>cmath</code> — Mathematical functions for complex numbers | 224 |
| 9.4 | <code>decimal</code> — Decimal fixed point and floating point arithmetic | 227 |
| 9.5 | <code>fractions</code> — Rational numbers | 253 |
| 9.6 | <code>random</code> — Generate pseudo-random numbers | 255 |
| 9.7 | <code>itertools</code> — Functions creating iterators for efficient looping | 259 |
| 9.8 | <code>functools</code> — Higher-order functions and operations on callable objects | 272 |
| 9.9 | <code>operator</code> — Standard operators as functions | 275 |
| 10 | File and Directory Access | 285 |
| 10.1 | <code>os.path</code> — Common pathname manipulations | 285 |
| 10.2 | <code>fileinput</code> — Iterate over lines from multiple input streams | 289 |
| 10.3 | <code>stat</code> — Interpreting <code>stat()</code> results | 291 |
| 10.4 | <code>statvfs</code> — Constants used with <code>os.statvfs()</code> | 295 |
| 10.5 | <code>filecmp</code> — File and Directory Comparisons | 295 |
| 10.6 | <code>tempfile</code> — Generate temporary files and directories | 298 |
| 10.7 | <code>glob</code> — Unix style pathname pattern expansion | 300 |
| 10.8 | <code>fnmatch</code> — Unix filename pattern matching | 301 |
| 10.9 | <code>linecache</code> — Random access to text lines | 302 |
| 10.10 | <code>shutil</code> — High-level file operations | 303 |
| 10.11 | <code>dircache</code> — Cached directory listings | 307 |
| 10.12 | <code>macpath</code> — Mac OS 9 path manipulation functions | 308 |
| 11 | Data Persistence | 309 |
| 11.1 | <code>pickle</code> — Python object serialization | 309 |
| 11.2 | <code>cPickle</code> — A faster pickle | 319 |
| 11.3 | <code>copy_reg</code> — Register pickle support functions | 320 |
| 11.4 | <code>shelve</code> — Python object persistence | 321 |
| 11.5 | <code>marshal</code> — Internal Python object serialization | 323 |
| 11.6 | <code>anydbm</code> — Generic access to DBM-style databases | 324 |
| 11.7 | <code>whichdb</code> — Guess which DBM module created a database | 326 |
| 11.8 | <code>dbm</code> — Simple “database” interface | 326 |

| | | |
|-----------|--|------------|
| 11.9 | <code>gdbm</code> — GNU's reinterpretation of <code>dbm</code> | 327 |
| 11.10 | <code>dbhash</code> — DBM-style interface to the BSD database library | 328 |
| 11.11 | <code>bsddb</code> — Interface to Berkeley DB library | 330 |
| 11.12 | <code>dumbdbm</code> — Portable DBM implementation | 332 |
| 11.13 | <code>sqlite3</code> — DB-API 2.0 interface for SQLite databases | 333 |
| 12 | Data Compression and Archiving | 353 |
| 12.1 | <code>zlib</code> — Compression compatible with <code>gzip</code> | 353 |
| 12.2 | <code>gzip</code> — Support for <code>gzip</code> files | 356 |
| 12.3 | <code>bz2</code> — Compression compatible with <code>bzip2</code> | 357 |
| 12.4 | <code>zipfile</code> — Work with ZIP archives | 360 |
| 12.5 | <code>tarfile</code> — Read and write tar archive files | 366 |
| 13 | File Formats | 377 |
| 13.1 | <code>csv</code> — CSV File Reading and Writing | 377 |
| 13.2 | <code>ConfigParser</code> — Configuration file parser | 385 |
| 13.3 | <code>robotparser</code> — Parser for <code>robots.txt</code> | 391 |
| 13.4 | <code>netrc</code> — <code>netrc</code> file processing | 392 |
| 13.5 | <code>xdrlib</code> — Encode and decode XDR data | 393 |
| 13.6 | <code>plistlib</code> — Generate and parse Mac OS X <code>.plist</code> files | 396 |
| 14 | Cryptographic Services | 399 |
| 14.1 | <code>hashlib</code> — Secure hashes and message digests | 399 |
| 14.2 | <code>hmac</code> — Keyed-Hashing for Message Authentication | 401 |
| 14.3 | <code>md5</code> — MD5 message digest algorithm | 402 |
| 14.4 | <code>sha</code> — SHA-1 message digest algorithm | 403 |
| 15 | Generic Operating System Services | 405 |
| 15.1 | <code>os</code> — Miscellaneous operating system interfaces | 405 |
| 15.2 | <code>io</code> — Core tools for working with streams | 434 |
| 15.3 | <code>time</code> — Time access and conversions | 445 |
| 15.4 | <code>argparse</code> — Parser for command-line options, arguments and sub-commands | 451 |
| 15.5 | <code>optparse</code> — Parser for command line options | 481 |
| 15.6 | <code>getopt</code> — C-style parser for command line options | 507 |
| 15.7 | <code>logging</code> — Logging facility for Python | 509 |
| 15.8 | <code>logging.config</code> — Logging configuration | 521 |
| 15.9 | <code>logging.handlers</code> — Logging handlers | 531 |
| 15.10 | <code>getpass</code> — Portable password input | 540 |
| 15.11 | <code>curses</code> — Terminal handling for character-cell displays | 540 |
| 15.12 | <code>curses.textpad</code> — Text input widget for <code>curses</code> programs | 557 |
| 15.13 | <code>curses.ascii</code> — Utilities for ASCII characters | 558 |
| 15.14 | <code>curses.panel</code> — A panel stack extension for <code>curses</code> | 561 |
| 15.15 | <code>platform</code> — Access to underlying platform's identifying data | 562 |
| 15.16 | <code>errno</code> — Standard <code>errno</code> system symbols | 565 |
| 15.17 | <code>ctypes</code> — A foreign function library for Python | 571 |
| 16 | Optional Operating System Services | 605 |
| 16.1 | <code>select</code> — Waiting for I/O completion | 605 |
| 16.2 | <code>threading</code> — Higher-level threading interface | 610 |
| 16.3 | <code>thread</code> — Multiple threads of control | 620 |
| 16.4 | <code>dummy_threading</code> — Drop-in replacement for the <code>threading</code> module | 621 |
| 16.5 | <code>dummy_thread</code> — Drop-in replacement for the <code>thread</code> module | 622 |
| 16.6 | <code>multiprocessing</code> — Process-based “threading” interface | 622 |
| 16.7 | <code>mmap</code> — Memory-mapped file support | 674 |
| 16.8 | <code>readline</code> — GNU <code>readline</code> interface | 677 |

| | | |
|-----------|---|------------|
| 16.9 | <code>rlcompleter</code> — Completion function for GNU readline | 681 |
| 17 | Interprocess Communication and Networking | 683 |
| 17.1 | <code>subprocess</code> — Subprocess management | 683 |
| 17.2 | <code>socket</code> — Low-level networking interface | 695 |
| 17.3 | <code>ssl</code> — TLS/SSL wrapper for socket objects | 707 |
| 17.4 | <code>signal</code> — Set handlers for asynchronous events | 731 |
| 17.5 | <code>popen2</code> — Subprocesses with accessible I/O streams | 734 |
| 17.6 | <code>asyncore</code> — Asynchronous socket handler | 736 |
| 17.7 | <code>asynchat</code> — Asynchronous socket command/response handler | 740 |
| 18 | Internet Data Handling | 745 |
| 18.1 | <code>email</code> — An email and MIME handling package | 745 |
| 18.2 | <code>json</code> — JSON encoder and decoder | 776 |
| 18.3 | <code>mailcap</code> — Mailcap file handling | 784 |
| 18.4 | <code>mailbox</code> — Manipulate mailboxes in various formats | 785 |
| 18.5 | <code>mhlib</code> — Access to MH mailboxes | 803 |
| 18.6 | <code>mimetools</code> — Tools for parsing MIME messages | 805 |
| 18.7 | <code>mimetypes</code> — Map filenames to MIME types | 807 |
| 18.8 | <code>MimeWriter</code> — Generic MIME file writer | 810 |
| 18.9 | <code>mimify</code> — MIME processing of mail messages | 810 |
| 18.10 | <code>multifile</code> — Support for files containing distinct parts | 811 |
| 18.11 | <code>rfc822</code> — Parse RFC 2822 mail headers | 814 |
| 18.12 | <code>base64</code> — RFC 3548: Base16, Base32, Base64 Data Encodings | 817 |
| 18.13 | <code>binhex</code> — Encode and decode binhex4 files | 819 |
| 18.14 | <code>binascii</code> — Convert between binary and ASCII | 820 |
| 18.15 | <code>quopri</code> — Encode and decode MIME quoted-printable data | 822 |
| 18.16 | <code>uu</code> — Encode and decode uuencode files | 822 |
| 19 | Structured Markup Processing Tools | 825 |
| 19.1 | <code>HTMLParser</code> — Simple HTML and XHTML parser | 825 |
| 19.2 | <code>sgmllib</code> — Simple SGML parser | 830 |
| 19.3 | <code>htmllib</code> — A parser for HTML documents | 833 |
| 19.4 | <code>htmlentitydefs</code> — Definitions of HTML general entities | 834 |
| 19.5 | <code>XML Processing Modules</code> | 835 |
| 19.6 | <code>XML vulnerabilities</code> | 835 |
| 19.7 | <code>xml.etree.ElementTree</code> — The ElementTree XML API | 836 |
| 19.8 | <code>xml.dom</code> — The Document Object Model API | 849 |
| 19.9 | <code>xml.dom.minidom</code> — Minimal DOM implementation | 860 |
| 19.10 | <code>xml.dom.pulldom</code> — Support for building partial DOM trees | 864 |
| 19.11 | <code>xml.sax</code> — Support for SAX2 parsers | 865 |
| 19.12 | <code>xml.sax.handler</code> — Base classes for SAX handlers | 867 |
| 19.13 | <code>xml.sax.saxutils</code> — SAX Utilities | 872 |
| 19.14 | <code>xml.sax.xmlreader</code> — Interface for XML parsers | 873 |
| 19.15 | <code>xml.parsers.expat</code> — Fast XML parsing using Expat | 876 |
| 20 | Internet Protocols and Support | 887 |
| 20.1 | <code>webbrowser</code> — Convenient Web-browser controller | 887 |
| 20.2 | <code>cgi</code> — Common Gateway Interface support | 889 |
| 20.3 | <code>cgitb</code> — Traceback manager for CGI scripts | 896 |
| 20.4 | <code>wsgiref</code> — WSGI Utilities and Reference Implementation | 897 |
| 20.5 | <code>urllib</code> — Open arbitrary resources by URL | 905 |
| 20.6 | <code>urllib2</code> — extensible library for opening URLs | 912 |
| 20.7 | <code>httplib</code> — HTTP protocol client | 923 |
| 20.8 | <code>ftplib</code> — FTP protocol client | 930 |

| | | |
|-----------|--|-------------|
| 20.9 | poplib — POP3 protocol client | 934 |
| 20.10 | imaplib — IMAP4 protocol client | 936 |
| 20.11 | nntplib — NNTP protocol client | 942 |
| 20.12 | smtplib — SMTP protocol client | 946 |
| 20.13 | smtpd — SMTP Server | 950 |
| 20.14 | telnetlib — Telnet client | 951 |
| 20.15 | uuid — UUID objects according to RFC 4122 | 954 |
| 20.16 | urlparse — Parse URLs into components | 957 |
| 20.17 | SocketServer — A framework for network servers | 961 |
| 20.18 | BaseHTTPServer — Basic HTTP server | 969 |
| 20.19 | SimpleHTTPServer — Simple HTTP request handler | 972 |
| 20.20 | CGIHTTPServer — CGI-capable HTTP request handler | 974 |
| 20.21 | cookielib — Cookie handling for HTTP clients | 975 |
| 20.22 | Cookie — HTTP state management | 983 |
| 20.23 | xmlrpclib — XML-RPC client access | 987 |
| 20.24 | SimpleXMLRPCServer — Basic XML-RPC server | 995 |
| 20.25 | DocXMLRPCServer — Self-documenting XML-RPC server | 999 |
| 21 | Multimedia Services | 1001 |
| 21.1 | audioop — Manipulate raw audio data | 1001 |
| 21.2 | imageop — Manipulate raw image data | 1004 |
| 21.3 | aifc — Read and write AIFF and AIFC files | 1005 |
| 21.4 | sunau — Read and write Sun AU files | 1007 |
| 21.5 | wave — Read and write WAV files | 1010 |
| 21.6 | chunk — Read IFF chunked data | 1012 |
| 21.7 | colorsys — Conversions between color systems | 1013 |
| 21.8 | imghdr — Determine the type of an image | 1014 |
| 21.9 | sndhdr — Determine type of sound file | 1015 |
| 21.10 | ossaudiodev — Access to OSS-compatible audio devices | 1015 |
| 22 | Internationalization | 1021 |
| 22.1 | gettext — Multilingual internationalization services | 1021 |
| 22.2 | locale — Internationalization services | 1030 |
| 23 | Program Frameworks | 1039 |
| 23.1 | cmd — Support for line-oriented command interpreters | 1039 |
| 23.2 | shlex — Simple lexical analysis | 1041 |
| 24 | Graphical User Interfaces with Tk | 1045 |
| 24.1 | Tkinter — Python interface to Tcl/Tk | 1045 |
| 24.2 | ttk — Tk themed widgets | 1056 |
| 24.3 | Tix — Extension widgets for Tk | 1074 |
| 24.4 | ScrolledText — Scrolled Text Widget | 1079 |
| 24.5 | turtle — Turtle graphics for Tk | 1079 |
| 24.6 | IDLE | 1109 |
| 24.7 | Other Graphical User Interface Packages | 1117 |
| 25 | Development Tools | 1119 |
| 25.1 | pydoc — Documentation generator and online help system | 1119 |
| 25.2 | doctest — Test interactive Python examples | 1120 |
| 25.3 | unittest — Unit testing framework | 1144 |
| 25.4 | 2to3 - Automated Python 2 to 3 code translation | 1169 |
| 25.5 | test — Regression tests package for Python | 1174 |
| 25.6 | test.support — Utility functions for tests | 1176 |

| | | |
|-----------|--|-------------|
| 26 | Debugging and Profiling | 1181 |
| 26.1 | bdb — Debugger framework | 1181 |
| 26.2 | pdb — The Python Debugger | 1185 |
| 26.3 | Debugger Commands | 1187 |
| 26.4 | The Python Profilers | 1190 |
| 26.5 | hotshot — High performance logging profiler | 1198 |
| 26.6 | timeit — Measure execution time of small code snippets | 1200 |
| 26.7 | trace — Trace or track Python statement execution | 1204 |
| 27 | Software Packaging and Distribution | 1207 |
| 27.1 | distutils — Building and installing Python modules | 1207 |
| 27.2 | ensurepip — Bootstrapping the pip installer | 1207 |
| 28 | Python Runtime Services | 1211 |
| 28.1 | sys — System-specific parameters and functions | 1211 |
| 28.2 | sysconfig — Provide access to Python’s configuration information | 1223 |
| 28.3 | __builtin__ — Built-in objects | 1226 |
| 28.4 | future_builtins — Python 3 builtins | 1227 |
| 28.5 | __main__ — Top-level script environment | 1228 |
| 28.6 | warnings — Warning control | 1228 |
| 28.7 | contextlib — Utilities for with-statement contexts | 1233 |
| 28.8 | abc — Abstract Base Classes | 1235 |
| 28.9 | atexit — Exit handlers | 1237 |
| 28.10 | traceback — Print or retrieve a stack traceback | 1239 |
| 28.11 | __future__ — Future statement definitions | 1243 |
| 28.12 | gc — Garbage Collector interface | 1244 |
| 28.13 | inspect — Inspect live objects | 1247 |
| 28.14 | site — Site-specific configuration hook | 1253 |
| 28.15 | user — User-specific configuration hook | 1255 |
| 28.16 | fpectl — Floating point exception control | 1256 |
| 29 | Custom Python Interpreters | 1259 |
| 29.1 | code — Interpreter base classes | 1259 |
| 29.2 | codeop — Compile Python code | 1261 |
| 30 | Restricted Execution | 1263 |
| 30.1 | rexec — Restricted execution framework | 1263 |
| 30.2 | Bastion — Restricting access to objects | 1267 |
| 31 | Importing Modules | 1269 |
| 31.1 | imp — Access the import internals | 1269 |
| 31.2 | importlib — Convenience wrappers for __import__() | 1272 |
| 31.3 | imputil — Import utilities | 1273 |
| 31.4 | zipimport — Import modules from Zip archives | 1276 |
| 31.5 | pkgutil — Package extension utility | 1278 |
| 31.6 | modulefinder — Find modules used by a script | 1280 |
| 31.7 | runpy — Locating and executing Python modules | 1282 |
| 32 | Python Language Services | 1285 |
| 32.1 | parser — Access Python parse trees | 1285 |
| 32.2 | ast — Abstract Syntax Trees | 1289 |
| 32.3 | symtable — Access to the compiler’s symbol tables | 1294 |
| 32.4 | symbol — Constants used with Python parse trees | 1296 |
| 32.5 | token — Constants used with Python parse trees | 1297 |
| 32.6 | keyword — Testing for Python keywords | 1298 |

| | | |
|-----------|---|-------------|
| 32.7 | <code>tokenize</code> — Tokenizer for Python source | 1298 |
| 32.8 | <code>tabnanny</code> — Detection of ambiguous indentation | 1300 |
| 32.9 | <code>pyclbr</code> — Python class browser support | 1301 |
| 32.10 | <code>py_compile</code> — Compile Python source files | 1302 |
| 32.11 | <code>compileall</code> — Byte-compile Python libraries | 1303 |
| 32.12 | <code>dis</code> — Disassembler for Python bytecode | 1304 |
| 32.13 | <code>pickletools</code> — Tools for pickle developers | 1313 |
| 33 | Python compiler package | 1315 |
| 33.1 | The basic interface | 1315 |
| 33.2 | Limitations | 1316 |
| 33.3 | Python Abstract Syntax | 1316 |
| 33.4 | Using Visitors to Walk ASTs | 1321 |
| 33.5 | Bytecode Generation | 1322 |
| 34 | Miscellaneous Services | 1323 |
| 34.1 | <code>formatter</code> — Generic output formatting | 1323 |
| 35 | MS Windows Specific Services | 1327 |
| 35.1 | <code>msilib</code> — Read and write Microsoft Installer files | 1327 |
| 35.2 | <code>msvcrt</code> — Useful routines from the MS VC++ runtime | 1332 |
| 35.3 | <code>_winreg</code> — Windows registry access | 1334 |
| 35.4 | <code>winsound</code> — Sound-playing interface for Windows | 1342 |
| 36 | Unix Specific Services | 1345 |
| 36.1 | <code>posix</code> — The most common POSIX system calls | 1345 |
| 36.2 | <code>pwd</code> — The password database | 1346 |
| 36.3 | <code>spwd</code> — The shadow password database | 1347 |
| 36.4 | <code>grp</code> — The group database | 1347 |
| 36.5 | <code>crypt</code> — Function to check Unix passwords | 1348 |
| 36.6 | <code>dl</code> — Call C functions in shared objects | 1349 |
| 36.7 | <code>termios</code> — POSIX style tty control | 1350 |
| 36.8 | <code>tty</code> — Terminal control functions | 1351 |
| 36.9 | <code>pty</code> — Pseudo-terminal utilities | 1351 |
| 36.10 | <code>fcntl</code> — The <code>fcntl</code> and <code>ioctl</code> system calls | 1352 |
| 36.11 | <code>pipes</code> — Interface to shell pipelines | 1354 |
| 36.12 | <code>posixfile</code> — File-like objects with locking support | 1355 |
| 36.13 | <code>resource</code> — Resource usage information | 1357 |
| 36.14 | <code>nis</code> — Interface to Sun's NIS (Yellow Pages) | 1360 |
| 36.15 | <code>syslog</code> — Unix syslog library routines | 1361 |
| 36.16 | <code>commands</code> — Utilities for running commands | 1362 |
| 37 | Mac OS X specific services | 1365 |
| 37.1 | <code>ic</code> — Access to the Mac OS X Internet Config | 1365 |
| 37.2 | <code>MacOS</code> — Access to Mac OS interpreter features | 1366 |
| 37.3 | <code>macostools</code> — Convenience routines for file manipulation | 1368 |
| 37.4 | <code>findertools</code> — The finder 's Apple Events interface | 1369 |
| 37.5 | <code>EasyDialogs</code> — Basic Macintosh dialogs | 1369 |
| 37.6 | <code>FrameWork</code> — Interactive application framework | 1372 |
| 37.7 | <code>autoGIL</code> — Global Interpreter Lock handling in event loops | 1375 |

While reference-index describes the exact syntax and semantics of the Python language, this library reference manual describes the standard library that is distributed with Python. It also describes some of the optional components that are commonly included in Python distributions.

Python's standard library is very extensive, offering a wide range of facilities as indicated by the long table of contents listed below. The library contains built-in modules (written in C) that provide access to system functionality such as file I/O that would otherwise be inaccessible to Python programmers, as well as modules written in Python that provide standardized solutions for many problems that occur in everyday programming. Some of these modules are explicitly designed to encourage and enhance the portability of Python programs by abstracting away platform-specifics into platform-neutral APIs.

The Python installers for the Windows platform usually include the entire standard library and often also include many additional components. For Unix-like operating systems Python is normally provided as a collection of packages, so it may be necessary to use the packaging tools provided with the operating system to obtain some or all of the optional components.

In addition to the standard library, there is a growing collection of several thousand components (from individual programs and modules to packages and entire application development frameworks), available from the [Python Package Index](#).

INTRODUCTION

The “Python library” contains several different kinds of components.

It contains data types that would normally be considered part of the “core” of a language, such as numbers and lists. For these types, the Python language core defines the form of literals and places some constraints on their semantics, but does not fully define the semantics. (On the other hand, the language core does define syntactic properties like the spelling and priorities of operators.)

The library also contains built-in functions and exceptions — objects that can be used by all Python code without the need of an `import` statement. Some of these are defined by the core language, but many are not essential for the core semantics and are only described here.

The bulk of the library, however, consists of a collection of modules. There are many ways to dissect this collection. Some modules are written in C and built in to the Python interpreter; others are written in Python and imported in source form. Some modules provide interfaces that are highly specific to Python, like printing a stack trace; some provide interfaces that are specific to particular operating systems, such as access to specific hardware; others provide interfaces that are specific to a particular application domain, like the World Wide Web. Some modules are available in all versions and ports of Python; others are only available when the underlying system supports or requires them; yet others are available only when a particular configuration option was chosen at the time when Python was compiled and installed.

This manual is organized “from the inside out:” it first describes the built-in data types, then the built-in functions and exceptions, and finally the modules, grouped in chapters of related modules. The ordering of the chapters as well as the ordering of the modules within each chapter is roughly from most relevant to least important.

This means that if you start reading this manual from the start, and skip to the next chapter when you get bored, you will get a reasonable overview of the available modules and application areas that are supported by the Python library. Of course, you don’t *have* to read it like a novel — you can also browse the table of contents (in front of the manual), or look for a specific function, module or term in the index (in the back). And finally, if you enjoy learning about random subjects, you choose a random page number (see module `random`) and read a section or two. Regardless of the order in which you read the sections of this manual, it helps to start with chapter *Built-in Functions*, as the remainder of the manual assumes familiarity with this material.

Let the show begin!

BUILT-IN FUNCTIONS

The Python interpreter has a number of functions built into it that are always available. They are listed here in alphabetical order.

| Built-in Functions | | | | |
|----------------------------|--------------------------|---------------------------|--------------------------|-----------------------------|
| <code>abs()</code> | <code>divmod()</code> | <code>input()</code> | <code>open()</code> | <code>staticmethod()</code> |
| <code>all()</code> | <code>enumerate()</code> | <code>int()</code> | <code>ord()</code> | <code>str()</code> |
| <code>any()</code> | <code>eval()</code> | <code>isinstance()</code> | <code>pow()</code> | <code>sum()</code> |
| <code>basestring()</code> | <code>execfile()</code> | <code>issubclass()</code> | <code>print()</code> | <code>super()</code> |
| <code>bin()</code> | <code>file()</code> | <code>iter()</code> | <code>property()</code> | <code>tuple()</code> |
| <code>bool()</code> | <code>filter()</code> | <code>len()</code> | <code>range()</code> | <code>type()</code> |
| <code>bytearray()</code> | <code>float()</code> | <code>list()</code> | <code>raw_input()</code> | <code>unichr()</code> |
| <code>callable()</code> | <code>format()</code> | <code>locals()</code> | <code>reduce()</code> | <code>unicode()</code> |
| <code>chr()</code> | <code>frozenset()</code> | <code>long()</code> | <code>reload()</code> | <code>vars()</code> |
| <code>classmethod()</code> | <code>getattr()</code> | <code>map()</code> | <code>repr()</code> | <code>xrange()</code> |
| <code>cmp()</code> | <code>globals()</code> | <code>max()</code> | <code>reversed()</code> | <code>zip()</code> |
| <code>compile()</code> | <code>hasattr()</code> | <code>memoryview()</code> | <code>round()</code> | <code>__import__()</code> |
| <code>complex()</code> | <code>hash()</code> | <code>min()</code> | <code>set()</code> | |
| <code>delattr()</code> | <code>help()</code> | <code>next()</code> | <code>setattr()</code> | |
| <code>dict()</code> | <code>hex()</code> | <code>object()</code> | <code>slice()</code> | |
| <code>dir()</code> | <code>id()</code> | <code>oct()</code> | <code>sorted()</code> | |

In addition, there are other four built-in functions that are no longer considered essential: `apply()`, `buffer()`, `coerce()`, and `intern()`. They are documented in the *Non-essential Built-in Functions* section.

abs(*x*)

Return the absolute value of a number. The argument may be a plain or long integer or a floating point number. If the argument is a complex number, its magnitude is returned.

all(*iterable*)

Return True if all elements of the *iterable* are true (or if the iterable is empty). Equivalent to:

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

New in version 2.5.

any(*iterable*)

Return True if any element of the *iterable* is true. If the iterable is empty, return False. Equivalent to:

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

New in version 2.5.

basestring()

This abstract type is the superclass for *str* and *unicode*. It cannot be called or instantiated, but it can be used to test whether an object is an instance of *str* or *unicode*. `isinstance(obj, basestring)` is equivalent to `isinstance(obj, (str, unicode))`.

New in version 2.3.

bin(x)

Convert an integer number to a binary string. The result is a valid Python expression. If *x* is not a Python *int* object, it has to define an `__index__()` method that returns an integer.

New in version 2.6.

class bool([x])

Return a Boolean value, i.e. one of *True* or *False*. *x* is converted using the standard truth testing procedure. If *x* is false or omitted, this returns *False*; otherwise it returns *True*. *bool* is also a class, which is a subclass of *int*. Class *bool* cannot be subclassed further. Its only instances are *False* and *True*.

New in version 2.2.1.

Changed in version 2.3: If no argument is given, this function returns *False*.

class bytearray([source[, encoding[, errors]]])

Return a new array of bytes. The *bytearray* class is a mutable sequence of integers in the range $0 \leq x < 256$. It has most of the usual methods of mutable sequences, described in *Mutable Sequence Types*, as well as most methods that the *str* type has, see *String Methods*.

The optional *source* parameter can be used to initialize the array in a few different ways:

- If it is *unicode*, you must also give the *encoding* (and optionally, *errors*) parameters; *bytearray()* then converts the unicode to bytes using `unicode.encode()`.
- If it is an *integer*, the array will have that size and will be initialized with null bytes.
- If it is an object conforming to the *buffer* interface, a read-only buffer of the object will be used to initialize the bytes array.
- If it is an *iterable*, it must be an iterable of integers in the range $0 \leq x < 256$, which are used as the initial contents of the array.

Without an argument, an array of size 0 is created.

New in version 2.6.

callable(object)

Return *True* if the *object* argument appears callable, *False* if not. If this returns true, it is still possible that a call fails, but if it is false, calling *object* will never succeed. Note that classes are callable (calling a class returns a new instance); class instances are callable if they have a `__call__()` method.

chr(i)

Return a string of one character whose ASCII code is the integer *i*. For example, `chr(97)` returns the string *'a'*. This is the inverse of `ord()`. The argument must be in the range [0..255], inclusive; *ValueError* will be raised if *i* is outside that range. See also `unichr()`.

classmethod (*function*)

Return a class method for *function*.

A class method receives the class as implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C(object):
    @classmethod
    def f(cls, arg1, arg2, ...):
        ...
```

The `@classmethod` form is a function *decorator* – see function for details.

A class method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see `staticmethod()`.

For more information on class methods, see types.

New in version 2.2.

Changed in version 2.4: Function decorator syntax added.

cmp (*x*, *y*)

Compare the two objects *x* and *y* and return an integer according to the outcome. The return value is negative if *x* < *y*, zero if *x* == *y* and strictly positive if *x* > *y*.

compile (*source*, *filename*, *mode* [, *flags* [, *dont_inherit*]])

Compile the *source* into a code or AST object. Code objects can be executed by an `exec` statement or evaluated by a call to `eval()`. *source* can either be a Unicode string, a *Latin-1* encoded string or an AST object. Refer to the `ast` module documentation for information on how to work with AST objects.

The *filename* argument should give the file from which the code was read; pass some recognizable value if it wasn't read from a file ('<string>' is commonly used).

The *mode* argument specifies what kind of code must be compiled; it can be 'exec' if *source* consists of a sequence of statements, 'eval' if it consists of a single expression, or 'single' if it consists of a single interactive statement (in the latter case, expression statements that evaluate to something other than `None` will be printed).

The optional arguments *flags* and *dont_inherit* control which future statements (see [PEP 236](#)) affect the compilation of *source*. If neither is present (or both are zero) the code is compiled with those future statements that are in effect in the code that is calling `compile()`. If the *flags* argument is given and *dont_inherit* is not (or is zero) then the future statements specified by the *flags* argument are used in addition to those that would be used anyway. If *dont_inherit* is a non-zero integer then the *flags* argument is it – the future statements in effect around the call to compile are ignored.

Future statements are specified by bits which can be bitwise ORed together to specify multiple statements. The bitfield required to specify a given feature can be found as the `compiler_flag` attribute on the `_Feature` instance in the `__future__` module.

This function raises `SyntaxError` if the compiled source is invalid, and `TypeError` if the source contains null bytes.

If you want to parse Python code into its AST representation, see `ast.parse()`.

Note: When compiling a string with multi-line code in 'single' or 'eval' mode, input must be terminated by at least one newline character. This is to facilitate detection of incomplete and complete statements in the `code`

module.

Changed in version 2.3: The *flags* and *dont_inherit* arguments were added.

Changed in version 2.6: Support for compiling AST objects.

Changed in version 2.7: Allowed use of Windows and Mac newlines. Also input in 'exec' mode does not have to end in a newline anymore.

class `complex` (*[real[, imag]]*)

Return a complex number with the value *real* + *imag**1j or convert a string or number to a complex number. If the first parameter is a string, it will be interpreted as a complex number and the function must be called without a second parameter. The second parameter can never be a string. Each argument may be any numeric type (including complex). If *imag* is omitted, it defaults to zero and the function serves as a numeric conversion function like `int()`, `long()` and `float()`. If both arguments are omitted, returns 0j.

Note: When converting from a string, the string must not contain whitespace around the central + or - operator. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises `ValueError`.

The complex type is described in *Numeric Types — int, float, long, complex*.

delattr (*object, name*)

This is a relative of `setattr()`. The arguments are an object and a string. The string must be the name of one of the object's attributes. The function deletes the named attribute, provided the object allows it. For example, `delattr(x, 'foobar')` is equivalent to `del x.foobar`.

class `dict` (***kwarg*)

class `dict` (*mapping, **kwarg*)

class `dict` (*iterable, **kwarg*)

Create a new dictionary. The *dict* object is the dictionary class. See *dict* and *Mapping Types — dict* for documentation about this class.

For other containers see the built-in *list*, *set*, and *tuple* classes, as well as the *collections* module.

dir (*[object]*)

Without arguments, return the list of names in the current local scope. With an argument, attempt to return a list of valid attributes for that object.

If the object has a method named `__dir__()`, this method will be called and must return the list of attributes. This allows objects that implement a custom `__getattr__()` or `__getattribute__()` function to customize the way `dir()` reports their attributes.

If the object does not provide `__dir__()`, the function tries its best to gather information from the object's `__dict__` attribute, if defined, and from its type object. The resulting list is not necessarily complete, and may be inaccurate when the object has a custom `__getattr__()`.

The default `dir()` mechanism behaves differently with different types of objects, as it attempts to produce the most relevant, rather than complete, information:

- If the object is a module object, the list contains the names of the module's attributes.
- If the object is a type or class object, the list contains the names of its attributes, and recursively of the attributes of its bases.
- Otherwise, the list contains the object's attributes' names, the names of its class's attributes, and recursively of the attributes of its class's base classes.

The resulting list is sorted alphabetically. For example:

```

>>> import struct
>>> dir()      # show the names in the module namespace
['__builtins__', '__doc__', '__name__', 'struct']
>>> dir(struct) # show the names in the struct module
['Struct', '__builtins__', '__doc__', '__file__', '__name__',
 '__package__', '_clearcache', 'calcsizes', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape(object):
    def __dir__(self):
        return ['area', 'perimeter', 'location']
>>> s = Shape()
>>> dir(s)
['area', 'perimeter', 'location']

```

Note: Because `dir()` is supplied primarily as a convenience for use at an interactive prompt, it tries to supply an interesting set of names more than it tries to supply a rigorously or consistently defined set of names, and its detailed behavior may change across releases. For example, metaclass attributes are not in the result list when the argument is a class.

divmod(*a*, *b*)

Take two (non complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using long division. With mixed operand types, the rules for binary arithmetic operators apply. For plain and long integers, the result is the same as $(a // b, a \% b)$. For floating point numbers the result is $(q, a \% b)$, where q is usually `math.floor(a / b)` but may be 1 less than that. In any case $q * b + a \% b$ is very close to a , if $a \% b$ is non-zero it has the same sign as b , and $0 \leq \text{abs}(a \% b) < \text{abs}(b)$.

Changed in version 2.3: Using `divmod()` with complex numbers is deprecated.

enumerate(*sequence*, *start*=0)

Return an enumerate object. *sequence* must be a sequence, an *iterator*, or some other object which supports iteration. The `next()` method of the iterator returned by `enumerate()` returns a tuple containing a count (from *start* which defaults to 0) and the values obtained from iterating over *sequence*:

```

>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]

```

Equivalent to:

```

def enumerate(sequence, start=0):
    n = start
    for elem in sequence:
        yield n, elem
        n += 1

```

New in version 2.3.

Changed in version 2.6: The *start* parameter was added.

eval(*expression*[, *globals*[, *locals*]])

The arguments are a Unicode or *Latin-1* encoded string and optional globals and locals. If provided, *globals* must be a dictionary. If provided, *locals* can be any mapping object.

Changed in version 2.4: formerly *locals* was required to be a dictionary.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* dictionaries as global and local namespace. If the *globals* dictionary is present and lacks `'__builtins__'`, the current globals are copied into *globals* before *expression* is parsed. This means that *expression* normally has full access to the standard `__builtin__` module and restricted environments are propagated. If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed in the environment where `eval()` is called. The return value is the result of the evaluated expression. Syntax errors are reported as exceptions. Example:

```
>>> x = 1
>>> print eval('x+1')
2
```

This function can also be used to execute arbitrary code objects (such as those created by `compile()`). In this case pass a code object instead of a string. If the code object has been compiled with `'exec'` as the *mode* argument, `eval()`'s return value will be `None`.

Hints: dynamic execution of statements is supported by the `exec` statement. Execution of statements from a file is supported by the `execfile()` function. The `globals()` and `locals()` functions returns the current global and local dictionary, respectively, which may be useful to pass around for use by `eval()` or `execfile()`.

See `ast.literal_eval()` for a function that can safely evaluate strings with expressions containing only literals.

execfile (*filename* [, *globals* [, *locals*]])

This function is similar to the `exec` statement, but parses a file instead of a string. It is different from the `import` statement in that it does not use the module administration — it reads the file unconditionally and does not create a new module.¹

The arguments are a file name and two optional dictionaries. The file is parsed and evaluated as a sequence of Python statements (similarly to a module) using the *globals* and *locals* dictionaries as global and local namespace. If provided, *locals* can be any mapping object. Remember that at module level, *globals* and *locals* are the same dictionary. If two separate objects are passed as *globals* and *locals*, the code will be executed as if it were embedded in a class definition.

Changed in version 2.4: formerly *locals* was required to be a dictionary.

If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed in the environment where `execfile()` is called. The return value is `None`.

Note: The default *locals* act as described for function `locals()` below: modifications to the default *locals* dictionary should not be attempted. Pass an explicit *locals* dictionary if you need to see effects of the code on *locals* after function `execfile()` returns. `execfile()` cannot be used reliably to modify a function's locals.

file (*name* [, *mode* [, *buffering*]])

Constructor function for the *file* type, described further in section *File Objects*. The constructor's arguments are the same as those of the `open()` built-in function described below.

When opening a file, it's preferable to use `open()` instead of invoking this constructor directly. *file* is more suited to type testing (for example, writing `isinstance(f, file)`).

New in version 2.2.

filter (*function*, *iterable*)

Construct a list from those elements of *iterable* for which *function* returns true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *iterable* is a string or a tuple, the result also has that type;

¹ It is used relatively rarely so does not warrant being made into a statement.

otherwise it is always a list. If *function* is `None`, the identity function is assumed, that is, all elements of *iterable* that are false are removed.

Note that `filter(function, iterable)` is equivalent to `[item for item in iterable if function(item)]` if *function* is not `None` and `[item for item in iterable if item]` if *function* is `None`.

See `itertools.ifilter()` and `itertools.ifilterfalse()` for iterator versions of this function, including a variation that filters for elements where the *function* returns false.

class `float` (`[x]`)

Return a floating point number constructed from a number or string *x*.

If the argument is a string, it must contain a possibly signed decimal or floating point number, possibly embedded in whitespace. The argument may also be `[+|-]nan` or `[+|-]inf`. Otherwise, the argument may be a plain or long integer or a floating point number, and a floating point number with the same value (within Python's floating point precision) is returned. If no argument is given, returns `0.0`.

Note: When passing in a string, values for NaN and Infinity may be returned, depending on the underlying C library. Float accepts the strings `nan`, `inf` and `-inf` for NaN and positive or negative infinity. The case and a leading `+` are ignored as well as a leading `-` is ignored for NaN. Float always represents NaN and infinity as `nan`, `inf` or `-inf`.

The float type is described in *Numeric Types — int, float, long, complex*.

format (*value* [, *format_spec*])

Convert a *value* to a “formatted” representation, as controlled by *format_spec*. The interpretation of *format_spec* will depend on the type of the *value* argument, however there is a standard formatting syntax that is used by most built-in types: *Format Specification Mini-Language*.

Note: `format(value, format_spec)` merely calls `value.__format__(format_spec)`.

New in version 2.6.

class `frozenset` (`[iterable]`)

Return a new *frozenset* object, optionally with elements taken from *iterable*. *frozenset* is a built-in class. See *frozenset* and *Set Types — set, frozenset* for documentation about this class.

For other containers see the built-in *set*, *list*, *tuple*, and *dict* classes, as well as the *collections* module.

New in version 2.4.

getattr (*object*, *name* [, *default*])

Return the value of the named attribute of *object*. *name* must be a string. If the string is the name of one of the object's attributes, the result is the value of that attribute. For example, `getattr(x, 'foobar')` is equivalent to `x.foobar`. If the named attribute does not exist, *default* is returned if provided, otherwise *AttributeError* is raised.

globals ()

Return a dictionary representing the current global symbol table. This is always the dictionary of the current module (inside a function or method, this is the module where it is defined, not the module from which it is called).

hasattr (*object*, *name*)

The arguments are an object and a string. The result is `True` if the string is the name of one of the object's attributes, `False` if not. (This is implemented by calling `getattr(object, name)` and seeing whether it raises an exception or not.)

hash (*object*)

Return the hash value of the object (if it has one). Hash values are integers. They are used to quickly compare dictionary keys during a dictionary lookup. Numeric values that compare equal have the same hash value (even if they are of different types, as is the case for 1 and 1.0).

help ([*object*])

Invoke the built-in help system. (This function is intended for interactive use.) If no argument is given, the interactive help system starts on the interpreter console. If the argument is a string, then the string is looked up as the name of a module, function, class, method, keyword, or documentation topic, and a help page is printed on the console. If the argument is any other kind of object, a help page on the object is generated.

This function is added to the built-in namespace by the `site` module.

New in version 2.2.

hex (*x*)

Convert an integer number (of any size) to a lowercase hexadecimal string prefixed with “0x”, for example:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
>>> hex(1L)
'0x1L'
```

If *x* is not a Python `int` or `long` object, it has to define a `__hex__()` method that returns a string.

See also `int()` for converting a hexadecimal string to an integer using a base of 16.

Note: To obtain a hexadecimal string representation for a float, use the `float.hex()` method.

Changed in version 2.4: Formerly only returned an unsigned literal.

id (*object*)

Return the “identity” of an object. This is an integer (or long integer) which is guaranteed to be unique and constant for this object during its lifetime. Two objects with non-overlapping lifetimes may have the same `id()` value.

CPython implementation detail: This is the address of the object in memory.

input ([*prompt*])

Equivalent to `eval(raw_input(prompt))`.

This function does not catch user errors. If the input is not syntactically valid, a `SyntaxError` will be raised. Other exceptions may be raised if there is an error during evaluation.

If the `readline` module was loaded, then `input()` will use it to provide elaborate line editing and history features.

Consider using the `raw_input()` function for general input from users.

class int (*x*=0)

class int (*x*, *base*=10)

Return an integer object constructed from a number or string *x*, or return 0 if no arguments are given. If *x* is a number, it can be a plain integer, a long integer, or a floating point number. If *x* is floating point, the conversion truncates towards zero. If the argument is outside the integer range, the function returns a long object instead.

If *x* is not a number or if *base* is given, then *x* must be a string or Unicode object representing an integer literal in radix *base*. Optionally, the literal can be preceded by + or – (with no space in between) and surrounded by whitespace. A base-*n* literal consists of the digits 0 to *n*-1, with a to z (or A to Z) having values 10 to 35. The default *base* is 10. The allowed values are 0 and 2–36. Base-2, -8, and -16 literals can be optionally prefixed with

0b/0B, 0o/0O/0, or 0x/0X, as with integer literals in code. Base 0 means to interpret the string exactly as an integer literal, so that the actual base is 2, 8, 10, or 16.

The integer type is described in *Numeric Types — int, float, long, complex*.

isinstance (*object*, *classinfo*)

Return true if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect or *virtual*) subclass thereof. Also return true if *classinfo* is a type object (new-style class) and *object* is an object of that type or of a (direct, indirect or *virtual*) subclass thereof. If *object* is not a class instance or an object of the given type, the function always returns false. If *classinfo* is a tuple of class or type objects (or recursively, other such tuples), return true if *object* is an instance of any of the classes or types. If *classinfo* is not a class, type, or tuple of classes, types, and such tuples, a *TypeError* exception is raised.

Changed in version 2.2: Support for a tuple of type information was added.

issubclass (*class*, *classinfo*)

Return true if *class* is a subclass (direct, indirect or *virtual*) of *classinfo*. A class is considered a subclass of itself. *classinfo* may be a tuple of class objects, in which case every entry in *classinfo* will be checked. In any other case, a *TypeError* exception is raised.

Changed in version 2.3: Support for a tuple of type information was added.

iter (*o*, *sentinel*)]

Return an *iterator* object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *o* must be a collection object which supports the iteration protocol (the `__iter__()` method), or it must support the sequence protocol (the `__getitem__()` method with integer arguments starting at 0). If it does not support either of those protocols, *TypeError* is raised. If the second argument, *sentinel*, is given, then *o* must be a callable object. The iterator created in this case will call *o* with no arguments for each call to its `next()` method; if the value returned is equal to *sentinel*, *StopIteration* will be raised, otherwise the value will be returned.

One useful application of the second form of `iter()` is to read lines of a file until a certain line is reached. The following example reads a file until the `readline()` method returns an empty string:

```
with open('mydata.txt') as fp:
    for line in iter(fp.readline, ''):
        process_line(line)
```

New in version 2.2.

len (*s*)

Return the length (the number of items) of an object. The argument may be a sequence (such as a string, bytes, tuple, list, or range) or a collection (such as a dictionary, set, or frozen set).

class list ([*iterable*])

Return a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For instance, `list('abc')` returns `['a', 'b', 'c']` and `list((1, 2, 3))` returns `[1, 2, 3]`. If no argument is given, returns a new empty list, `[]`.

`list` is a mutable sequence type, as documented in *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*. For other containers see the built in *dict*, *set*, and *tuple* classes, and the *collections* module.

locals ()

Update and return a dictionary representing the current local symbol table. Free variables are returned by `locals()` when it is called in function blocks, but not in class blocks.

Note: The contents of this dictionary should not be modified; changes may not affect the values of local and free

variables used by the interpreter.

class `long` (*x*=0)

class `long` (*x*, *base*=10)

Return a long integer object constructed from a string or number *x*. If the argument is a string, it must contain a possibly signed number of arbitrary size, possibly embedded in whitespace. The *base* argument is interpreted in the same way as for `int()`, and may only be given when *x* is a string. Otherwise, the argument may be a plain or long integer or a floating point number, and a long integer with the same value is returned. Conversion of floating point numbers to integers truncates (towards zero). If no arguments are given, returns 0L.

The long type is described in *Numeric Types — int, float, long, complex*.

map (*function*, *iterable*, ...)

Apply *function* to every item of *iterable* and return a list of the results. If additional *iterable* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. If one iterable is shorter than another it is assumed to be extended with None items. If *function* is None, the identity function is assumed; if there are multiple arguments, `map()` returns a list consisting of tuples containing the corresponding items from all iterables (a kind of transpose operation). The *iterable* arguments may be a sequence or any iterable object; the result is always a list.

max (*iterable*[, *key*])

max (*arg1*, *arg2*, **args*[, *key*])

Return the largest item in an iterable or the largest of two or more arguments.

If one positional argument is provided, *iterable* must be a non-empty iterable (such as a non-empty string, tuple or list). The largest item in the iterable is returned. If two or more positional arguments are provided, the largest of the positional arguments is returned.

The optional *key* argument specifies a one-argument ordering function like that used for `list.sort()`. The *key* argument, if supplied, must be in keyword form (for example, `max(a, b, c, key=func)`).

Changed in version 2.5: Added support for the optional *key* argument.

memoryview (*obj*)

Return a “memory view” object created from the given argument. See *memoryview type* for more information.

min (*iterable*[, *key*])

min (*arg1*, *arg2*, **args*[, *key*])

Return the smallest item in an iterable or the smallest of two or more arguments.

If one positional argument is provided, *iterable* must be a non-empty iterable (such as a non-empty string, tuple or list). The smallest item in the iterable is returned. If two or more positional arguments are provided, the smallest of the positional arguments is returned.

The optional *key* argument specifies a one-argument ordering function like that used for `list.sort()`. The *key* argument, if supplied, must be in keyword form (for example, `min(a, b, c, key=func)`).

Changed in version 2.5: Added support for the optional *key* argument.

next (*iterator*[, *default*])

Retrieve the next item from the *iterator* by calling its `next()` method. If *default* is given, it is returned if the iterator is exhausted, otherwise *StopIteration* is raised.

New in version 2.6.

class `object`

Return a new featureless object. *object* is a base for all new style classes. It has the methods that are common to all instances of new style classes.

New in version 2.2.

Changed in version 2.3: This function does not accept any arguments. Formerly, it accepted arguments but ignored them.

oct (*x*)

Convert an integer number (of any size) to an octal string. The result is a valid Python expression.

Changed in version 2.4: Formerly only returned an unsigned literal.

open (*name* [, *mode* [, *buffering*]])

Open a file, returning an object of the *file* type described in section *File Objects*. If the file cannot be opened, *IOError* is raised. When opening a file, it's preferable to use *open()* instead of invoking the *file* constructor directly.

The first two arguments are the same as for *stdio*'s *fopen()*: *name* is the file name to be opened, and *mode* is a string indicating how the file is to be opened.

The most commonly-used values of *mode* are 'r' for reading, 'w' for writing (truncating the file if it already exists), and 'a' for appending (which on *some* Unix systems means that *all* writes append to the end of the file regardless of the current seek position). If *mode* is omitted, it defaults to 'r'. The default is to use text mode, which may convert '\n' characters to a platform-specific representation on writing and back on reading. Thus, when opening a binary file, you should append 'b' to the *mode* value to open the file in binary mode, which will improve portability. (Appending 'b' is useful even on systems that don't treat binary and text files differently, where it serves as documentation.) See below for more possible values of *mode*.

The optional *buffering* argument specifies the file's desired buffer size: 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size (in bytes). A negative *buffering* means to use the system default, which is usually line buffered for tty devices and fully buffered for other files. If omitted, the system default is used.²

Modes 'r+', 'w+' and 'a+' open the file for updating (reading and writing); note that 'w+' truncates the file. Append 'b' to the mode to open the file in binary mode, on systems that differentiate between binary and text files; on systems that don't have this distinction, adding the 'b' has no effect.

In addition to the standard *fopen()* values *mode* may be 'U' or 'rU'. Python is usually built with *universal newlines* support; supplying 'U' opens the file as a text file, but lines may be terminated by any of the following: the Unix end-of-line convention '\n', the Macintosh convention '\r', or the Windows convention '\r\n'. All of these external representations are seen as '\n' by the Python program. If Python is built without universal newlines support a *mode* with 'U' is the same as normal text mode. Note that file objects so opened also have an attribute called *newlines* which has a value of *None* (if no newlines have yet been seen), '\n', '\r', '\r\n', or a tuple containing all the newline types seen.

Python enforces that the mode, after stripping 'U', begins with 'r', 'w' or 'a'.

Python provides many file handling modules including *fileinput*, *os*, *os.path*, *tempfile*, and *shutil*.

Changed in version 2.5: Restriction on first letter of mode string introduced.

ord (*c*)

Given a string of length one, return an integer representing the Unicode code point of the character when the argument is a unicode object, or the value of the byte when the argument is an 8-bit string. For example, *ord('a')* returns the integer 97, *ord(u'\u2020')* returns 8224. This is the inverse of *chr()* for 8-bit strings and of *unichr()* for unicode objects. If a unicode argument is given and Python was built with UCS2 Unicode, then the character's code point must be in the range [0..65535] inclusive; otherwise the string length is two, and a *TypeError* will be raised.

pow (*x*, *y* [, *z*])

Return *x* to the power *y*; if *z* is present, return *x* to the power *y*, modulo *z* (computed more efficiently than *pow(x,*

² Specifying a buffer size currently has no effect on systems that don't have *setvbuf()*. The interface to specify the buffer size is not done using a method that calls *setvbuf()*, because that may dump core when called after any I/O has been performed, and there's no reliable way to determine whether this is the case.

$y) \% z$). The two-argument form `pow(x, y)` is equivalent to using the power operator: `x**y`.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For int and long int operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `10**2` returns `100`, but `10**-2` returns `0.01`. (This last feature was added in Python 2.2. In Python 2.1 and before, if both arguments were of integer types and the second argument was negative, an exception was raised.) If the second argument is negative, the third argument must be omitted. If `z` is present, `x` and `y` must be of integer types, and `y` must be non-negative. (This restriction was added in Python 2.2. In Python 2.1 and before, floating 3-argument `pow()` returned platform-dependent results depending on floating-point rounding accidents.)

print (*objects, sep=' ', end='\n', file=sys.stdout)

Print *objects* to the stream *file*, separated by *sep* and followed by *end*. *sep*, *end* and *file*, if present, must be given as keyword arguments.

All non-keyword arguments are converted to strings like `str()` does and written to the stream, separated by *sep* and followed by *end*. Both *sep* and *end* must be strings; they can also be `None`, which means to use the default values. If no *objects* are given, `print()` will just write *end*.

The *file* argument must be an object with a `write(string)` method; if it is not present or `None`, `sys.stdout` will be used. Output buffering is determined by *file*. Use `file.flush()` to ensure, for instance, immediate appearance on a screen.

Note: This function is not normally available as a built-in since the name `print` is recognized as the `print` statement. To disable the statement and use the `print()` function, use this future statement at the top of your module:

```
from __future__ import print_function
```

New in version 2.6.

class property ([*fget* [, *fset* [, *fdel* [, *doc*]]]])

Return a property attribute for *new-style classes* (classes that derive from *object*).

fget is a function for getting an attribute value. *fset* is a function for setting an attribute value. *fdel* is a function for deleting an attribute value. And *doc* creates a docstring for the attribute.

A typical use is to define a managed attribute `x`:

```
class C(object):
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

    x = property(getx, setx, delx, "I'm the 'x' property.")
```

If `c` is an instance of `C`, `c.x` will invoke the getter, `c.x = value` will invoke the setter and `del c.x` the deleter.

If given, *doc* will be the docstring of the property attribute. Otherwise, the property will copy *fget*'s docstring (if it exists). This makes it possible to create read-only properties easily using `property()` as a *decorator*:

```
class Parrot(object):
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage
```

The `@property` decorator turns the `voltage()` method into a “getter” for a read-only attribute with the same name, and it sets the docstring for `voltage` to “Get the current voltage.”

A property object has `getter`, `setter`, and `deleter` methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```
class C(object):
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (`x` in this case.)

The returned property object also has the attributes `fget`, `fset`, and `fdel` corresponding to the constructor arguments.

New in version 2.2.

Changed in version 2.5: Use *fget*'s docstring if no *doc* given.

Changed in version 2.6: The `getter`, `setter`, and `deleter` attributes were added.

range (*stop*)

range (*start*, *stop* [, *step*])

This is a versatile function to create lists containing arithmetic progressions. It is most often used in `for` loops. The arguments must be plain integers. If the *step* argument is omitted, it defaults to 1. If the *start* argument is omitted, it defaults to 0. The full form returns a list of plain integers [*start*, *start* + *step*, *start* + 2 * *step*, ...]. If *step* is positive, the last element is the largest *start* + *i* * *step* less than *stop*; if *step* is negative, the last element is the smallest *start* + *i* * *step* greater than *stop*. *step* must not be zero (or else `ValueError` is raised). Example:

```
>>> range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

(continues on next page)

(continued from previous page)

```

>>> range(1, 11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> range(0, 30, 5)
[0, 5, 10, 15, 20, 25]
>>> range(0, 10, 3)
[0, 3, 6, 9]
>>> range(0, -10, -1)
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> range(0)
[]
>>> range(1, 0)
[]

```

raw_input ([*prompt*])

If the *prompt* argument is present, it is written to standard output without a trailing newline. The function then reads a line from input, converts it to a string (stripping a trailing newline), and returns that. When EOF is read, *EOFError* is raised. Example:

```

>>> s = raw_input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"

```

If the *readline* module was loaded, then *raw_input()* will use it to provide elaborate line editing and history features.

reduce (*function*, *iterable* [, *initializer*])

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, *reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])* calculates *(((1+2)+3)+4)+5*. The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initializer* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initializer* is not given and *iterable* contains only one item, the first item is returned. Roughly equivalent to:

```

def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        try:
            initializer = next(it)
        except StopIteration:
            raise TypeError('reduce() of empty sequence with no initial value')
    accum_value = initializer
    for x in it:
        accum_value = function(accum_value, x)
    return accum_value

```

reload (*module*)

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (the same as the *module* argument).

When *reload(module)* is executed:

- Python modules' code is recompiled and the module-level code reexecuted, defining a new set of objects which are bound to names in the module's dictionary. The *init* function of extension modules is not called a second time.

- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects — with a `try` statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it — one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (`module.*name*`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

repr (*object*)

Return a string containing a printable representation of an object. This is the same value yielded by conversions (reverse quotes). It is sometimes useful to be able to access this operation as an ordinary function. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to `eval()`, otherwise the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method.

reversed (*seq*)

Return a reverse *iterator*. *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at 0).

New in version 2.4.

Changed in version 2.6: Added the possibility to write a custom `__reversed__()` method.

round (*number* [, *ndigits*])

Return the floating point value *number* rounded to *ndigits* digits after the decimal point. If *ndigits* is omitted, it defaults to zero. The result is a floating point number. Values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done away from 0 (so, for example, `round(0.5)` is 1.0 and `round(-0.5)` is -1.0).

Note: The behavior of `round()` for floats can be surprising: for example, `round(2.675, 2)` gives 2.67 instead of the expected 2.68. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See [tut-fp-issues](#) for more information.

class set ([*iterable*])

Return a new *set* object, optionally with elements taken from *iterable*. *set* is a built-in class. See [set](#) and [Set](#)

Types — *set*, *frozenset* for documentation about this class.

For other containers see the built-in *frozenset*, *list*, *tuple*, and *dict* classes, as well as the *collections* module.

New in version 2.4.

setattr (*object*, *name*, *value*)

This is the counterpart of *getattr()*. The arguments are an object, a string and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, *setattr(x, 'foobar', 123)* is equivalent to *x.foobar = 123*.

class slice (*stop*)

class slice (*start*, *stop* [, *step*])

Return a *slice* object representing the set of indices specified by *range(start, stop, step)*. The *start* and *step* arguments default to *None*. Slice objects have read-only data attributes *start*, *stop* and *step* which merely return the argument values (or their default). They have no other explicit functionality; however they are used by Numerical Python and other third party extensions. Slice objects are also generated when extended indexing syntax is used. For example: *a[start:stop:step]* or *a[start:stop, i]*. See *itertools.islice()* for an alternate version that returns an iterator.

sorted (*iterable* [, *cmp* [, *key* [, *reverse*]]])

Return a new sorted list from the items in *iterable*.

The optional arguments *cmp*, *key*, and *reverse* have the same meaning as those for the *list.sort()* method (described in section *Mutable Sequence Types*).

cmp specifies a custom comparison function of two arguments (iterable elements) which should return a negative, zero or positive number depending on whether the first argument is considered smaller than, equal to, or larger than the second argument: *cmp=lambda x, y: cmp(x.lower(), y.lower())*. The default value is *None*.

key specifies a function of one argument that is used to extract a comparison key from each list element: *key=str.lower*. The default value is *None* (compare the elements directly).

reverse is a boolean value. If set to *True*, then the list elements are sorted as if each comparison were reversed.

In general, the *key* and *reverse* conversion processes are much faster than specifying an equivalent *cmp* function. This is because *cmp* is called multiple times for each list element while *key* and *reverse* touch each element only once. Use *functools.cmp_to_key()* to convert an old-style *cmp* function to a *key* function.

The built-in *sorted()* function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

For sorting examples and a brief sorting tutorial, see *sortinghowto*.

New in version 2.4.

staticmethod (*function*)

Return a static method for *function*.

A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C(object):
    @staticmethod
    def f(arg1, arg2, ...):
        ...
```

The *@staticmethod* form is a function *decorator* — see function for details.

A static method can be called either on the class (such as *C.f()*) or on an instance (such as *C().f()*).

Static methods in Python are similar to those found in Java or C++. Also see `classmethod()` for a variant that is useful for creating alternate class constructors.

For more information on static methods, see `types`.

New in version 2.2.

Changed in version 2.4: Function decorator syntax added.

class `str` (*object*="")

Return a string containing a nicely printable representation of an object. For strings, this returns the string itself. The difference with `repr(object)` is that `str(object)` does not always attempt to return a string that is acceptable to `eval()`; its goal is to return a printable string. If no argument is given, returns the empty string, ''.

For more information on strings see *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* which describes sequence functionality (strings are sequences), and also the string-specific methods described in the *String Methods* section. To output formatted strings use template strings or the `%` operator described in the *String Formatting Operations* section. In addition see the *String Services* section. See also `unicode()`.

sum (*iterable* [, *start*])

Sums *start* and the items of an *iterable* from left to right and returns the total. *start* defaults to 0. The *iterable*'s items are normally numbers, and the start value is not allowed to be a string.

For some use cases, there are good alternatives to `sum()`. The preferred, fast way to concatenate a sequence of strings is by calling `''.join(sequence)`. To add floating point values with extended precision, see `math.fsum()`. To concatenate a series of iterables, consider using `itertools.chain()`.

New in version 2.3.

super (*type* [, *object-or-type*])

Return a proxy object that delegates method calls to a parent or sibling class of *type*. This is useful for accessing inherited methods that have been overridden in a class. The search order is same as that used by `getattr()` except that the *type* itself is skipped.

The `__mro__` attribute of the *type* lists the method resolution search order used by both `getattr()` and `super()`. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

If the second argument is omitted, the super object returned is unbound. If the second argument is an object, `isinstance(obj, type)` must be true. If the second argument is a type, `issubclass(type2, type)` must be true (this is useful for classmethods).

Note: `super()` only works for *new-style classes*.

There are two typical use cases for *super*. In a class hierarchy with single inheritance, *super* can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of *super* in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement “diamond diagrams” where multiple base classes implement the same method. Good design dictates that this method have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
        super(C, self).method(arg)
```

Note that `super()` is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattr__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, `super()` is undefined for implicit lookups using statements or operators such as `super()[name]`.

Also note that `super()` is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references.

For practical suggestions on how to design cooperative classes using `super()`, see [guide to using super\(\)](#).

New in version 2.2.

tuple (*[iterable]*)

Return a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is returned unchanged. For instance, `tuple('abc')` returns ('a', 'b', 'c') and `tuple([1, 2, 3])` returns (1, 2, 3). If no argument is given, returns a new empty tuple, `()`.

`tuple` is an immutable sequence type, as documented in [Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange](#). For other containers see the built in `dict`, `list`, and `set` classes, and the `collections` module.

class type (*object*)

class type (*name, bases, dict*)

With one argument, return the type of an *object*. The return value is a type object. The `isinstance()` built-in function is recommended for testing the type of an object.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute; the *bases* tuple itemizes the base classes and becomes the `__bases__` attribute; and the *dict* dictionary is the namespace containing definitions for class body and becomes the `__dict__` attribute. For example, the following two statements create identical `type` objects:

```
>>> class X(object):
...     a = 1
...
>>> X = type('X', (object,), dict(a=1))
```

New in version 2.2.

unichr (*i*)

Return the Unicode string of one character whose Unicode code is the integer *i*. For example, `unichr(97)` returns the string `u'a'`. This is the inverse of `ord()` for Unicode strings. The valid range for the argument depends how Python was configured – it may be either UCS2 [0..0xFFFF] or UCS4 [0..0x10FFFF]. `ValueError` is raised otherwise. For ASCII and 8-bit strings see `chr()`.

New in version 2.0.

unicode (*object=""*)

unicode (*object[, encoding[, errors]]*)

Return the Unicode string version of *object* using one of the following modes:

If *encoding* and/or *errors* are given, `unicode()` will decode the object which can either be an 8-bit string or a character buffer using the codec for *encoding*. The *encoding* parameter is a string giving the name of an encoding; if the encoding is not known, `LookupError` is raised. Error handling is done according to *errors*; this specifies the treatment of characters which are invalid in the input encoding. If *errors* is 'strict' (the default), a `ValueError` is raised on errors, while a value of 'ignore' causes errors to be silently ignored, and a value of

'replace' causes the official Unicode replacement character, U+FFFD, to be used to replace input characters which cannot be decoded. See also the *codecs* module.

If no optional parameters are given, `unicode()` will mimic the behaviour of `str()` except that it returns Unicode strings instead of 8-bit strings. More precisely, if *object* is a Unicode string or subclass it will return that Unicode string without any additional decoding applied.

For objects which provide a `__unicode__()` method, it will call this method without arguments to create a Unicode string. For all other objects, the 8-bit string version or representation is requested and then converted to a Unicode string using the codec for the default encoding in 'strict' mode.

For more information on Unicode strings see *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* which describes sequence functionality (Unicode strings are sequences), and also the string-specific methods described in the *String Methods* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. In addition see the *String Services* section. See also `str()`.

New in version 2.0.

Changed in version 2.2: Support for `__unicode__()` added.

vars(*[object]*)

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, new-style classes use a dictproxy to prevent direct dictionary updates).

Without an argument, `vars()` acts like `locals()`. Note, the locals dictionary is only useful for reads since updates to the locals dictionary are ignored.

xrange(*stop*)

xrange(*start, stop[, step]*)

This function is very similar to `range()`, but returns an *xrange object* instead of a list. This is an opaque sequence type which yields the same values as the corresponding list, without actually storing them all simultaneously. The advantage of `xrange()` over `range()` is minimal (since `xrange()` still has to create the values when asked for them) except when a very large range is used on a memory-starved machine or when all of the range's elements are never used (such as when the loop is usually terminated with `break`). For more information on xrange objects, see *XRange Type* and *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*.

CPython implementation detail: `xrange()` is intended to be simple and fast. Implementations may impose restrictions to achieve this. The C implementation of Python restricts all arguments to native C longs ("short" Python integers), and also requires that the number of elements fit in a native C long. If a larger range is needed, an alternate version can be crafted using the *itertools* module: `islice(count(start, step), (stop-start+step-1+2*(step<0))//step)`.

zip(*[iterable, ...]*)

This function returns a list of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument sequences or iterables. The returned list is truncated in length to the length of the shortest argument sequence. When there are multiple arguments which are all of the same length, `zip()` is similar to `map()` with an initial argument of `None`. With a single sequence argument, it returns a list of 1-tuples. With no arguments, it returns an empty list.

The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `zip(*[iter(s)]*n)`.

`zip()` in conjunction with the `*` operator can be used to unzip a list:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> zipped = zip(x, y)
```

(continues on next page)

(continued from previous page)

```
>>> zipped
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zipped)
>>> x == list(x2) and y == list(y2)
True
```

New in version 2.0.

Changed in version 2.4: Formerly, `zip()` required at least one argument and `zip()` raised a `TypeError` instead of returning an empty list.

`__import__(name[, globals[, locals[, fromlist[, level]]])`

Note: This is an advanced function that is not needed in everyday Python programming, unlike `importlib.import_module()`.

This function is invoked by the `import` statement. It can be replaced (by importing the `__builtin__` module and assigning to `__builtin__.__import__`) in order to change semantics of the `import` statement, but nowadays it is usually simpler to use import hooks (see [PEP 302](#)). Direct use of `__import__()` is rare, except in cases where you want to import a module whose name is only known at runtime.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all, and uses its *globals* only to determine the package context of the `import` statement.

level specifies whether to use absolute or relative imports. The default is `-1` which indicates both absolute and relative imports will be attempted. `0` means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling `__import__()`.

When the *name* variable is of the form `package.module`, normally, the top-level package (the name up till the first dot) is returned, *not* the module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.

For example, the statement `import spam` results in bytecode resembling the following code:

```
spam = __import__('spam', globals(), locals(), [], -1)
```

The statement `import spam.ham` results in this call:

```
spam = __import__('spam.ham', globals(), locals(), [], -1)
```

Note how `__import__()` returns the toplevel module here because this is the object that is bound to a name by the `import` statement.

On the other hand, the statement `from spam.ham import eggs, sausage as saus` results in

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], -1)
eggs = _temp.eggs
saus = _temp.sausage
```

Here, the `spam.ham` module is returned from `__import__()`. From this object, the names to import are retrieved and assigned to their respective names.

If you simply want to import a module (potentially within a package) by name, use `importlib.import_module()`.

Changed in version 2.5: The level parameter was added.

Changed in version 2.5: Keyword support for parameters was added.

NON-ESSENTIAL BUILT-IN FUNCTIONS

There are several built-in functions that are no longer essential to learn, know or use in modern Python programming. They have been kept here to maintain backwards compatibility with programs written for older versions of Python.

Python programmers, trainers, students and book writers should feel free to bypass these functions without concerns about missing something important.

apply (*function*, *args*[, *keywords*])

The *function* argument must be a callable object (a user-defined or built-in function or method, or a class object) and the *args* argument must be a sequence. The *function* is called with *args* as the argument list; the number of arguments is the length of the tuple. If the optional *keywords* argument is present, it must be a dictionary whose keys are strings. It specifies keyword arguments to be added to the end of the argument list. Calling *apply()* is different from just calling *function(args)*, since in that case there is always exactly one argument. The use of *apply()* is equivalent to *function(*args, **keywords)*.

Deprecated since version 2.3: Use *function(*args, **keywords)* instead of *apply(function, args, keywords)* (see *tut-unpacking-arguments*).

buffer (*object*[, *offset*[, *size*]])

The *object* argument must be an object that supports the buffer call interface (such as strings, arrays, and buffers). A new buffer object will be created which references the *object* argument. The buffer object will be a slice from the beginning of *object* (or from the specified *offset*). The slice will extend to the end of *object* (or will have a length given by the *size* argument).

coerce (*x*, *y*)

Return a tuple consisting of the two numeric arguments converted to a common type, using the same rules as used by arithmetic operations. If coercion is not possible, raise *TypeError*.

intern (*string*)

Enter *string* in the table of “interned” strings and return the interned string – which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup – if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Changed in version 2.3: Interned strings are not immortal (like they used to be in Python 2.2 and before); you must keep a reference to the return value of *intern()* around to benefit from it.

BUILT-IN CONSTANTS

A small number of constants live in the built-in namespace. They are:

False

The false value of the *bool* type.

New in version 2.3.

True

The true value of the *bool* type.

New in version 2.3.

None

The sole value of *types.NoneType*. *None* is frequently used to represent the absence of a value, as when default arguments are not passed to a function.

Changed in version 2.4: Assignments to *None* are illegal and raise a *SyntaxError*.

NotImplemented

Special value which can be returned by the “rich comparison” special methods (*__eq__()*, *__lt__()*, and friends), to indicate that the comparison is not implemented with respect to the other type.

Ellipsis

Special value used in conjunction with extended slicing syntax.

__debug__

This constant is true if Python was not started with an *-O* option. See also the *assert* statement.

Note: The names *None* and *__debug__* cannot be reassigned (assignments to them, even as an attribute name, raise *SyntaxError*), so they can be considered “true” constants.

Changed in version 2.7: Assignments to *__debug__* as an attribute became illegal.

4.1 Constants added by the *site* module

The *site* module (which is imported automatically during startup, except if the *-S* command-line option is given) adds several constants to the built-in namespace. They are useful for the interactive interpreter shell and should not be used in programs.

```
quit ([code=None])  
exit ([code=None])
```

Objects that when printed, print a message like “Use quit() or Ctrl-D (i.e. EOF) to exit”, and when called, raise *SystemExit* with the specified exit code.

copyright

credits

Objects that when printed or called, print the text of copyright or credits, respectively.

license

Object that when printed, prints the message “Type license() to see the full license text”, and when called, displays the full license text in a pager-like fashion (one screen at a time).

BUILT-IN TYPES

The following sections describe the standard types that are built into the interpreter.

Note: Historically (until release 2.2), Python’s built-in types have differed from user-defined types because it was not possible to use the built-in types as the basis for object-oriented inheritance. This limitation no longer exists.

The principal built-in types are numerics, sequences, mappings, files, classes, instances and exceptions.

Some operations are supported by several object types; in particular, practically all objects can be compared, tested for truth value, and converted to a string (with the `repr()` function or the slightly different `str()` function). The latter function is implicitly used when an object is written by the `print()` function.

5.1 Truth Value Testing

Any object can be tested for truth value, for use in an `if` or `while` condition or as operand of the Boolean operations below. The following values are considered false:

- `None`
- `False`
- zero of any numeric type, for example, `0`, `0L`, `0.0`, `0j`.
- any empty sequence, for example, `''`, `()`, `[]`.
- any empty mapping, for example, `{}`.
- instances of user-defined classes, if the class defines a `__nonzero__()` or `__len__()` method, when that method returns the integer zero or `bool` value `False`.¹

All other values are considered true — so objects of many types are always true.

Operations and built-in functions that have a Boolean result always return `0` or `False` for false and `1` or `True` for true, unless otherwise stated. (Important exception: the Boolean operations `or` and `and` always return one of their operands.)

5.2 Boolean Operations — `and`, `or`, `not`

These are the Boolean operations, ordered by ascending priority:

¹ Additional information on these special methods may be found in the Python Reference Manual (customization).

| Operation | Result | Notes |
|----------------------|--|-------|
| <code>x or y</code> | if <i>x</i> is false, then <i>y</i> , else <i>x</i> | (1) |
| <code>x and y</code> | if <i>x</i> is false, then <i>x</i> , else <i>y</i> | (2) |
| <code>not x</code> | if <i>x</i> is false, then <code>True</code> , else <code>False</code> | (3) |

Notes:

- (1) This is a short-circuit operator, so it only evaluates the second argument if the first one is false.
- (2) This is a short-circuit operator, so it only evaluates the second argument if the first one is true.
- (3) `not` has a lower priority than non-Boolean operators, so `not a == b` is interpreted as `not (a == b)`, and `a == not b` is a syntax error.

5.3 Comparisons

Comparison operations are supported by all objects. They all have the same priority (which is higher than that of the Boolean operations). Comparisons can be chained arbitrarily; for example, `x < y <= z` is equivalent to `x < y` and `y <= z`, except that *y* is evaluated only once (but in both cases *z* is not evaluated at all when `x < y` is found to be false).

This table summarizes the comparison operations:

| Operation | Meaning | Notes |
|---------------------|-------------------------|-------|
| <code><</code> | strictly less than | |
| <code><=</code> | less than or equal | |
| <code>></code> | strictly greater than | |
| <code>>=</code> | greater than or equal | |
| <code>==</code> | equal | |
| <code>!=</code> | not equal | (1) |
| <code>is</code> | object identity | |
| <code>is not</code> | negated object identity | |

Notes:

- (1) `!=` can also be written `<>`, but this is an obsolete usage kept for backwards compatibility only. New code should always use `!=`.

Objects of different types, except different numeric types and different string types, never compare equal; such objects are ordered consistently but arbitrarily (so that sorting a heterogeneous array yields a consistent result). Furthermore, some types (for example, file objects) support only a degenerate notion of comparison where any two objects of that type are unequal. Again, such objects are ordered arbitrarily but consistently. The `<`, `<=`, `>` and `>=` operators will raise a *TypeError* exception when any operand is a complex number.

Non-identical instances of a class normally compare as non-equal unless the class defines the `__eq__()` method or the `__cmp__()` method.

Instances of a class cannot be ordered with respect to other instances of the same class, or other types of object, unless the class defines either enough of the rich comparison methods (`__lt__()`, `__le__()`, `__gt__()`, and `__ge__()`) or the `__cmp__()` method.

CPython implementation detail: Objects of different types except numbers are ordered by their type names; objects of the same types that don't support proper comparison are ordered by their address.

Two more operations with the same syntactic priority, `in` and `not in`, are supported only by sequence types (below).

5.4 Numeric Types — int, float, long, complex

There are four distinct numeric types: *plain integers*, *long integers*, *floating point numbers*, and *complex numbers*. In addition, Booleans are a subtype of plain integers. Plain integers (also just called *integers*) are implemented using `long` in C, which gives them at least 32 bits of precision (`sys.maxint` is always set to the maximum plain integer value for the current platform, the minimum value is `-sys.maxint - 1`). Long integers have unlimited precision. Floating point numbers are usually implemented using `double` in C; information about the precision and internal representation of floating point numbers for the machine on which your program is running is available in `sys.float_info`. Complex numbers have a real and imaginary part, which are each a floating point number. To extract these parts from a complex number `z`, use `z.real` and `z.imag`. (The standard library includes additional numeric types, *fractions* that hold rationals, and *decimal* that hold floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including binary, hex, and octal numbers) yield plain integers unless the value they denote is too large to be represented as a plain integer, in which case they yield a long integer. Integer literals with an `'L'` or `'l'` suffix yield long integers (`'L'` is preferred because `11` looks too much like eleven!). Numeric literals containing a decimal point or an exponent sign yield floating point numbers. Appending `'j'` or `'J'` to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Python fully supports mixed arithmetic: when a binary arithmetic operator has operands of different numeric types, the operand with the “narrower” type is widened to that of the other, where plain integer is narrower than long integer is narrower than floating point is narrower than complex. Comparisons between numbers of mixed type use the same rule.² The constructors `int()`, `long()`, `float()`, and `complex()` can be used to produce numbers of a specific type.

All built-in numeric types support the following operations. See power and later sections for the operators’ priorities.

| Operation | Result | Notes |
|------------------------------|--|--------|
| <code>x + y</code> | sum of <i>x</i> and <i>y</i> | |
| <code>x - y</code> | difference of <i>x</i> and <i>y</i> | |
| <code>x * y</code> | product of <i>x</i> and <i>y</i> | |
| <code>x / y</code> | quotient of <i>x</i> and <i>y</i> | (1) |
| <code>x // y</code> | (floored) quotient of <i>x</i> and <i>y</i> | (4)(5) |
| <code>x % y</code> | remainder of <i>x</i> / <i>y</i> | (4) |
| <code>-x</code> | <i>x</i> negated | |
| <code>+x</code> | <i>x</i> unchanged | |
| <code>abs(x)</code> | absolute value or magnitude of <i>x</i> | (3) |
| <code>int(x)</code> | <i>x</i> converted to integer | (2) |
| <code>long(x)</code> | <i>x</i> converted to long integer | (2) |
| <code>float(x)</code> | <i>x</i> converted to floating point | (6) |
| <code>complex(re, im)</code> | a complex number with real part <i>re</i> , imaginary part <i>im</i> . <i>im</i> defaults to zero. | |
| <code>c.conjugate()</code> | conjugate of the complex number <i>c</i> . (Identity on real numbers) | |
| <code>divmod(x, y)</code> | the pair (<i>x</i> // <i>y</i> , <i>x</i> % <i>y</i>) | (3)(4) |
| <code>pow(x, y)</code> | <i>x</i> to the power <i>y</i> | (3)(7) |
| <code>x ** y</code> | <i>x</i> to the power <i>y</i> | (7) |

Notes:

- (1) For (plain or long) integer division, the result is an integer. The result is always rounded towards minus infinity: `1/2` is 0, `(-1)/2` is -1, `1/(-2)` is -1, and `(-1)/(-2)` is 0. Note that the result is a long integer if either operand is a long integer, regardless of the numeric value.

² As a consequence, the list `[1, 2]` is considered equal to `[1.0, 2.0]`, and similarly for tuples.

- (2) Conversion from floats using `int()` or `long()` truncates toward zero like the related function, `math.trunc()`. Use the function `math.floor()` to round downward and `math.ceil()` to round upward.
- (3) See *Built-in Functions* for a full description.
- (4) Deprecated since version 2.3: The floor division operator, the modulo operator, and the `divmod()` function are no longer defined for complex numbers. Instead, convert to a floating point number using the `abs()` function if appropriate.
- (5) Also referred to as integer division. The resultant value is a whole integer, though the result's type is not necessarily `int`.
- (6) float also accepts the strings “nan” and “inf” with an optional prefix “+” or “-” for Not a Number (NaN) and positive or negative infinity.

New in version 2.6.

- (7) Python defines `pow(0, 0)` and `0 ** 0` to be 1, as is common for programming languages.

All *numbers.Real* types (`int`, `long`, and `float`) also include the following operations:

| Operation | Result |
|----------------------------|--|
| <code>math.trunc(x)</code> | <code>x</code> truncated to <i>Integral</i> |
| <code>round(x[, n])</code> | <code>x</code> rounded to <code>n</code> digits, rounding ties away from zero. If <code>n</code> is omitted, it defaults to 0. |
| <code>math.floor(x)</code> | the greatest integer as a float $\leq x$ |
| <code>math.ceil(x)</code> | the least integer as a float $\geq x$ |

5.4.1 Bitwise Operations on Integer Types

Bitwise operations only make sense for integers. Negative numbers are treated as their 2's complement value (this assumes a sufficiently large number of bits that no overflow occurs during the operation).

The priorities of the binary bitwise operations are all lower than the numeric operations and higher than the comparisons; the unary operation `~` has the same priority as the other unary numeric operations (`+` and `-`).

This table lists the bitwise operations sorted in ascending priority:

| Operation | Result | Notes |
|---------------------------|--|--------|
| <code>x y</code> | bitwise <i>or</i> of <code>x</code> and <code>y</code> | |
| <code>x ^ y</code> | bitwise <i>exclusive or</i> of <code>x</code> and <code>y</code> | |
| <code>x & y</code> | bitwise <i>and</i> of <code>x</code> and <code>y</code> | |
| <code>x << n</code> | <code>x</code> shifted left by <code>n</code> bits | (1)(2) |
| <code>x >> n</code> | <code>x</code> shifted right by <code>n</code> bits | (1)(3) |
| <code>~x</code> | the bits of <code>x</code> inverted | |

Notes:

- (1) Negative shift counts are illegal and cause a `ValueError` to be raised.
- (2) A left shift by `n` bits is equivalent to multiplication by `pow(2, n)`. A long integer is returned if the result exceeds the range of plain integers.
- (3) A right shift by `n` bits is equivalent to division by `pow(2, n)`.

5.4.2 Additional Methods on Integer Types

The integer types implement the `numbers.Integral` abstract base class. In addition, they provide one more method:

`int.bit_length()`

`long.bit_length()`

Return the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

More precisely, if `x` is nonzero, then `x.bit_length()` is the unique positive integer `k` such that $2^{k-1} \leq \text{abs}(x) < 2^k$. Equivalently, when `abs(x)` is small enough to have a correctly rounded logarithm, then `k = 1 + int(log(abs(x), 2))`. If `x` is zero, then `x.bit_length()` returns 0.

Equivalent to:

```
def bit_length(self):
    s = bin(self)           # binary representation: bin(-37) --> '-0b100101'
    s = s.lstrip('-0b')     # remove leading zeros and minus sign
    return len(s)           # len('100101') --> 6
```

New in version 2.7.

5.4.3 Additional Methods on Float

The float type implements the `numbers.Real` abstract base class. float also has the following additional methods.

`float.as_integer_ratio()`

Return a pair of integers whose ratio is exactly equal to the original float and with a positive denominator. Raises `OverflowError` on infinities and a `ValueError` on NaNs.

New in version 2.6.

`float.is_integer()`

Return True if the float instance is finite with integral value, and False otherwise:

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

New in version 2.6.

Two methods support conversion to and from hexadecimal strings. Since Python's floats are stored internally as binary numbers, converting a float to or from a *decimal* string usually involves a small rounding error. In contrast, hexadecimal strings allow exact representation and specification of floating-point numbers. This can be useful when debugging, and in numerical work.

`float.hex()`

Return a representation of a floating-point number as a hexadecimal string. For finite floating-point numbers, this representation will always include a leading 0x and a trailing p and exponent.

New in version 2.6.

`float.fromhex(s)`

Class method to return the float represented by a hexadecimal string *s*. The string *s* may have leading and trailing whitespace.

New in version 2.6.

Note that `float.hex()` is an instance method, while `float.fromhex()` is a class method.

A hexadecimal string takes the form:

`[sign] ['0x'] integer ['.' fraction] ['p' exponent]`

where the optional *sign* may be either + or -, *integer* and *fraction* are strings of hexadecimal digits, and *exponent* is a decimal integer with an optional leading sign. Case is not significant, and there must be at least one hexadecimal digit in either the integer or the fraction. This syntax is similar to the syntax specified in section 6.4.4.2 of the C99 standard, and also to the syntax used in Java 1.5 onwards. In particular, the output of `float.hex()` is usable as a hexadecimal floating-point literal in C or Java code, and hexadecimal strings produced by C's %a format character or Java's `Double.toHexString` are accepted by `float.fromhex()`.

Note that the exponent is written in decimal rather than hexadecimal, and that it gives the power of 2 by which to multiply the coefficient. For example, the hexadecimal string `0x3.a7p10` represents the floating-point number $(3 + 10./16 + 7./16**2) * 2.0**10$, or 3740.0:

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

Applying the reverse conversion to 3740.0 gives a different hexadecimal string representing the same number:

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

5.5 Iterator Types

New in version 2.2.

Python supports a concept of iteration over containers. This is implemented using two distinct methods; these are used to allow user-defined classes to support iteration. Sequences, described below in more detail, always support the iteration methods.

One method needs to be defined for container objects to provide iteration support:

`container.__iter__()`

Return an iterator object. The object is required to support the iterator protocol described below. If a container supports different types of iteration, additional methods can be provided to specifically request iterators for those iteration types. (An example of an object supporting multiple forms of iteration would be a tree structure which supports both breadth-first and depth-first traversal.) This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

The iterator objects themselves are required to support the following two methods, which together form the *iterator protocol*:

`iterator.__iter__()`

Return the iterator object itself. This is required to allow both containers and iterators to be used with the `for` and `in` statements. This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

```
iterator.next()
```

Return the next item from the container. If there are no further items, raise the *StopIteration* exception. This method corresponds to the `tp_iternext` slot of the type structure for Python objects in the Python/C API.

Python defines several iterator objects to support iteration over general and specific sequence types, dictionaries, and other more specialized forms. The specific types are not important beyond their implementation of the iterator protocol.

The intention of the protocol is that once an iterator's *next()* method raises *StopIteration*, it will continue to do so on subsequent calls. Implementations that do not obey this property are deemed broken. (This constraint was added in Python 2.3; in Python 2.2, various iterators are broken according to this rule.)

5.5.1 Generator Types

Python's *generators* provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and *next()* methods. More information about generators can be found in the documentation for the *yield* expression.

5.6 Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange

There are seven sequence types: strings, Unicode strings, lists, tuples, bytearrays, buffers, and xrange objects.

For other containers see the built in *dict* and *set* classes, and the *collections* module.

String literals are written in single or double quotes: `'xyzyzy'`, `"frobozz"`. See strings for more about string literals. Unicode strings are much like strings, but are specified in the syntax using a preceding `'u'` character: `u'abc'`, `u"def"`. In addition to the functionality described here, there are also string-specific methods described in the *String Methods* section. Lists are constructed with square brackets, separating items with commas: `[a, b, c]`. Tuples are constructed by the comma operator (not within square brackets), with or without enclosing parentheses, but an empty tuple must have the enclosing parentheses, such as `a, b, c` or `()`. A single item tuple must have a trailing comma, such as `(d,)`.

Bytearray objects are created with the built-in function *bytearray()*.

Buffer objects are not directly supported by Python syntax, but can be created by calling the built-in function *buffer()*. They don't support concatenation or repetition.

Objects of type *xrange* are similar to buffers in that there is no specific syntax to create them, but they are created using the *xrange()* function. They don't support slicing, concatenation or repetition, and using *in*, *not in*, *min()* or *max()* on them is inefficient.

Most sequence types support the following operations. The *in* and *not in* operations have the same priorities as the comparison operations. The *+* and *** operations have the same priority as the corresponding numeric operations.³ Additional methods are provided for *Mutable Sequence Types*.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type; *n*, *i* and *j* are integers:

³ They must have since the parser can't tell the type of the operands.

| Operation | Result | Notes |
|---------------------------|--|--------|
| <code>x in s</code> | True if an item of <i>s</i> is equal to <i>x</i> , else False | (1) |
| <code>x not in s</code> | False if an item of <i>s</i> is equal to <i>x</i> , else True | (1) |
| <code>s + t</code> | the concatenation of <i>s</i> and <i>t</i> | (6) |
| <code>s * n, n * s</code> | equivalent to adding <i>s</i> to itself <i>n</i> times | (2) |
| <code>s[i]</code> | <i>i</i> th item of <i>s</i> , origin 0 | (3) |
| <code>s[i:j]</code> | slice of <i>s</i> from <i>i</i> to <i>j</i> | (3)(4) |
| <code>s[i:j:k]</code> | slice of <i>s</i> from <i>i</i> to <i>j</i> with step <i>k</i> | (3)(5) |
| <code>len(s)</code> | length of <i>s</i> | |
| <code>min(s)</code> | smallest item of <i>s</i> | |
| <code>max(s)</code> | largest item of <i>s</i> | |
| <code>s.index(x)</code> | index of the first occurrence of <i>x</i> in <i>s</i> | |
| <code>s.count(x)</code> | total number of occurrences of <i>x</i> in <i>s</i> | |

Sequence types also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see comparisons in the language reference.)

Notes:

- (1) When *s* is a string or Unicode string object the `in` and `not in` operations act like a substring test. In Python versions before 2.3, *x* had to be a string of length 1. In Python 2.3 and beyond, *x* may be a string of any length.
- (2) Values of *n* less than 0 are treated as 0 (which yields an empty sequence of the same type as *s*). Note that items in the sequence *s* are not copied; they are referenced multiple times. This often haunts new Python programmers; consider:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

What has happened is that `[]` is a one-element list containing an empty list, so all three elements of `[] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Further explanation is available in the FAQ entry [faq-multidimensional-list](#).

- (3) If *i* or *j* is negative, the index is relative to the end of sequence *s*: `len(s) + i` or `len(s) + j` is substituted. But note that `-0` is still 0.
- (4) The slice of *s* from *i* to *j* is defined as the sequence of items with index *k* such that `i <= k < j`. If *i* or *j* is greater than `len(s)`, use `len(s)`. If *i* is omitted or None, use 0. If *j* is omitted or None, use `len(s)`. If *i* is greater than or equal to *j*, the slice is empty.
- (5) The slice of *s* from *i* to *j* with step *k* is defined as the sequence of items with index `x = i + n*k` such that `0 <= n < (j-i)/k`. In other words, the indices are *i*, *i+k*, *i+2*k*, *i+3*k* and so on, stopping when *j* is reached (but never including *j*). When *k* is positive, *i* and *j* are reduced to `len(s)` if they are greater. When *k* is negative,

i and j are reduced to $\text{len}(s) - 1$ if they are greater. If i or j are omitted or `None`, they become “end” values (which end depends on the sign of k). Note, k cannot be zero. If k is `None`, it is treated like 1.

- (6) **CPython implementation detail:** If s and t are both strings, some Python implementations such as CPython can usually perform an in-place optimization for assignments of the form $s = s + t$ or $s += t$. When applicable, this optimization makes quadratic run-time much less likely. This optimization is both version and implementation dependent. For performance sensitive code, it is preferable to use the `str.join()` method which assures consistent linear concatenation performance across versions and implementations.

Changed in version 2.4: Formerly, string concatenation never occurred in-place.

5.6.1 String Methods

Below are listed the string methods which both 8-bit strings and Unicode objects support. Some of them are also available on `bytearray` objects.

In addition, Python’s strings support the sequence type methods described in the *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* section. To output formatted strings use template strings or the `%` operator described in the *String Formatting Operations* section. Also, see the `re` module for string functions based on regular expressions.

`str.capitalize()`

Return a copy of the string with its first character capitalized and the rest lowercased.

For 8-bit strings, this method is locale-dependent.

`str.center(width[, fillchar])`

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is a space).

Changed in version 2.4: Support for the *fillchar* argument.

`str.count(sub[, start[, end]])`

Return the number of non-overlapping occurrences of substring *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

`str.decode([encoding[, errors]])`

Decodes the string using the codec registered for *encoding*. *encoding* defaults to the default string encoding. *errors* may be given to set a different error handling scheme. The default is 'strict', meaning that encoding errors raise a `UnicodeError`. Other possible values are 'ignore', 'replace' and any other name registered via `codecs.register_error()`, see section *Codec Base Classes*.

New in version 2.2.

Changed in version 2.3: Support for other error handling schemes added.

Changed in version 2.7: Support for keyword arguments added.

`str.encode([encoding[, errors]])`

Return an encoded version of the string. Default encoding is the current default string encoding. *errors* may be given to set a different error handling scheme. The default for *errors* is 'strict', meaning that encoding errors raise a `UnicodeError`. Other possible values are 'ignore', 'replace', 'xmlcharrefreplace', 'backslashreplace' and any other name registered via `codecs.register_error()`, see section *Codec Base Classes*. For a list of possible encodings, see section *Standard Encodings*.

New in version 2.0.

Changed in version 2.3: Support for 'xmlcharrefreplace' and 'backslashreplace' and other error handling schemes added.

Changed in version 2.7: Support for keyword arguments added.

`str.endswith(suffix[, start[, end]])`

Return `True` if the string ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

Changed in version 2.5: Accept tuples as *suffix*.

`str.expandtabs([tabsize])`

Return a copy of the string where all tab characters are replaced by one or more spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* characters (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the string, the current column is set to zero and the string is examined character by character. If the character is a tab (`\t`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the character is a newline (`\n`) or return (`\r`), it is copied and the current column is reset to zero. Any other character is copied unchanged and the current column is incremented by one regardless of how the character is represented when printed.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123  01234'
```

`str.find(sub[, start[, end]])`

Return the lowest index in the string where substring *sub* is found within the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

Note: The `find()` method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> 'Py' in 'Python'
True
```

`str.format(*args, **kwargs)`

Perform a string formatting operation. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`. Each replacement field contains either the numeric index of a positional argument, or the name of a keyword argument. Returns a copy of the string where each replacement field is replaced with the string value of the corresponding argument.

```
>>> "The sum of 1 + 2 is {}".format(1+2)
'The sum of 1 + 2 is 3'
```

See [Format String Syntax](#) for a description of the various formatting options that can be specified in format strings.

This method of string formatting is the new standard in Python 3, and should be preferred to the `%` formatting described in [String Formatting Operations](#) in new code.

New in version 2.6.

`str.index(sub[, start[, end]])`

Like `find()`, but raise `ValueError` when the substring is not found.

`str.isalnum()`

Return true if all characters in the string are alphanumeric and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.isalpha()`

Return true if all characters in the string are alphabetic and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.isdigit()`

Return true if all characters in the string are digits and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.islower()`

Return true if all cased characters⁴ in the string are lowercase and there is at least one cased character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.isspace()`

Return true if there are only whitespace characters in the string and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.istitle()`

Return true if the string is a titlecased string and there is at least one character, for example uppercase characters may only follow uncased characters and lowercase characters only cased ones. Return false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.isupper()`

Return true if all cased characters⁴ in the string are uppercase and there is at least one cased character, false otherwise.

For 8-bit strings, this method is locale-dependent.

`str.join(iterable)`

Return a string which is the concatenation of the strings in *iterable*. If there is any Unicode object in *iterable*, return a Unicode instead. A `TypeError` will be raised if there are any non-string or non Unicode object values in *iterable*. The separator between elements is the string providing this method.

`str.ljust(width[, fillchar])`

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is a space). The original string is returned if *width* is less than or equal to `len(s)`.

Changed in version 2.4: Support for the *fillchar* argument.

`str.lower()`

Return a copy of the string with all the cased characters⁴ converted to lowercase.

For 8-bit strings, this method is locale-dependent.

`str.lstrip([chars])`

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> '  spacious  '.lstrip()
'spacious  '
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

Changed in version 2.2.2: Support for the *chars* argument.

`str.partition(sep)`

Split the string at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the

⁴ Cased characters are those with general category property being one of “Lu” (Letter, uppercase), “Ll” (Letter, lowercase), or “Lt” (Letter, titlecase).

separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing the string itself, followed by two empty strings.

New in version 2.5.

`str.replace(old, new[, count])`

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

`str.rfind(sub[, start[, end]])`

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within *s[start:end]*. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

`str.rindex(sub[, start[, end]])`

Like `rfind()` but raises `ValueError` when the substring *sub* is not found.

`str.rjust(width[, fillchar])`

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is a space). The original string is returned if *width* is less than or equal to `len(s)`.

Changed in version 2.4: Support for the *fillchar* argument.

`str.rpartition(sep)`

Split the string at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty strings, followed by the string itself.

New in version 2.5.

`str.rsplit([sep[, maxsplit]])`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any whitespace string is a separator. Except for splitting from the right, `rsplit()` behaves like `split()` which is described in detail below.

New in version 2.4.

`str.rstrip([chars])`

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

Changed in version 2.2.2: Support for the *chars* argument.

`str.split([sep[, maxsplit]])`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters (for example, `'1<>2<>3'.split('<>')` returns `['1', '2', '3']`). Splitting an empty string with a specified separator returns `['']`.

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the string has

leading or trailing whitespace. Consequently, splitting an empty string or a string consisting of just whitespace with a `None` separator returns `[]`.

For example, `' 1 2 3 '.split()` returns `['1', '2', '3']`, and `' 1 2 3 '.split(None, 1)` returns `['1', '2 3 ']`.

str.splitlines([*keepends*])

Return a list of the lines in the string, breaking at line boundaries. This method uses the *universal newlines* approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

Python recognizes `"\r"`, `"\n"`, and `"\r\n"` as line boundaries for 8-bit strings.

For example:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Unlike `split()` when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

For comparison, `split('\n')` gives:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

unicode.splitlines([*keepends*])

Return a list of the lines in the string, like `str.splitlines()`. However, the Unicode method splits on the following line boundaries, which are a superset of the *universal newlines* recognized for 8-bit strings.

| Representation | Description |
|--------------------------------------|-----------------------------|
| <code>\n</code> | Line Feed |
| <code>\r</code> | Carriage Return |
| <code>\r\n</code> | Carriage Return + Line Feed |
| <code>\v</code> or <code>\x0b</code> | Line Tabulation |
| <code>\f</code> or <code>\x0c</code> | Form Feed |
| <code>\x1c</code> | File Separator |
| <code>\x1d</code> | Group Separator |
| <code>\x1e</code> | Record Separator |
| <code>\x85</code> | Next Line (C1 Control Code) |
| <code>\u2028</code> | Line Separator |
| <code>\u2029</code> | Paragraph Separator |

Changed in version 2.7: `\v` and `\f` added to list of line boundaries.

str.startswith(*prefix*[, *start*[, *end*]])

Return `True` if string starts with the *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test string beginning at that position. With optional *end*, stop comparing string at that position.

Changed in version 2.5: Accept tuples as *prefix*.

`str.strip([chars])`

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

Changed in version 2.2.2: Support for the *chars* argument.

`str.swapcase()`

Return a copy of the string with uppercase characters converted to lowercase and vice versa.

For 8-bit strings, this method is locale-dependent.

`str.title()`

Return a titlecased version of the string where words start with an uppercase character and the remaining characters are lowercase.

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The Uk'
```

A workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+(' [A-Za-z]+)?",
...                    lambda mo: mo.group(0)[0].upper() +
...                               mo.group(0)[1:].lower(),
...                    s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

For 8-bit strings, this method is locale-dependent.

`str.translate(table[, deletechars])`

Return a copy of the string where all characters occurring in the optional argument *deletechars* are removed, and the remaining characters have been mapped through the given translation table, which must be a string of length 256.

You can use the `maketrans()` helper function in the `string` module to create a translation table. For string objects, set the *table* argument to `None` for translations that only delete characters:

```
>>> 'read this short text'.translate(None, 'aeiou')
'rd ths shrt txt'
```

New in version 2.6: Support for a `None` *table* argument.

For Unicode objects, the `translate()` method does not accept the optional *deletechars* argument. Instead, it returns a copy of the *s* where all characters have been mapped through the given translation table which must be a mapping of Unicode ordinals to Unicode ordinals, Unicode strings or `None`. Unmapped characters are left

untouched. Characters mapped to `None` are deleted. Note, a more flexible approach is to create a custom character mapping codec using the `codecs` module (see `encodings.cp1251` for an example).

`str.upper()`

Return a copy of the string with all the cased characters⁴ converted to uppercase. Note that `s.upper().isupper()` might be `False` if `s` contains uncased characters or if the Unicode category of the resulting character(s) is not “Lu” (Letter, uppercase), but e.g. “Lt” (Letter, titlecase).

For 8-bit strings, this method is locale-dependent.

`str.zfill(width)`

Return the numeric string left filled with zeros in a string of length *width*. A sign prefix is handled correctly. The original string is returned if *width* is less than or equal to `len(s)`.

New in version 2.2.2.

The following methods are present only on unicode objects:

`unicode.isnumeric()`

Return `True` if there are only numeric characters in `S`, `False` otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH.

`unicode.isdecimal()`

Return `True` if there are only decimal characters in `S`, `False` otherwise. Decimal characters include digit characters, and all characters that can be used to form decimal-radix numbers, e.g. U+0660, ARABIC-INDIC DIGIT ZERO.

5.6.2 String Formatting Operations

String and Unicode objects have one unique built-in operation: the `%` operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given `format % values` (where *format* is a string or Unicode object), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to the using `sprintf()` in the C language. If *format* is a Unicode object, or if any of the objects being converted using the `%s` conversion are Unicode objects, the result will also be a Unicode object.

If *format* requires a single argument, *values* may be a single non-tuple object.⁵ Otherwise, *values* must be a tuple with exactly the number of items specified by the format string, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual width is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the string *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

⁵ To format only a tuple you should therefore provide a singleton tuple whose only element is the tuple to be formatted.

```
>>> print '%(language)s has %(number)03d quote types.' % \
...      {"language": "Python", "number": 2}
Python has 002 quote types.
```

In this case no * specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

| Flag | Meaning |
|------|--|
| '#' | The value conversion will use the “alternate form” (where defined below). |
| '0' | The conversion will be zero padded for numeric values. |
| '-' | The converted value is left adjusted (overrides the '0' conversion if both are given). |
| ' ' | (a space) A blank should be left before a positive number (or empty string) produced by a signed conversion. |
| '+' | A sign character ('+' or '-') will precede the conversion (overrides a “space” flag). |

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python – so e.g. %ld is identical to %d.

The conversion types are:

| Conversion | Meaning | Notes |
|------------|--|-------|
| 'd' | Signed integer decimal. | |
| 'i' | Signed integer decimal. | |
| 'o' | Signed octal value. | (1) |
| 'u' | Obsolete type – it is identical to 'd'. | (7) |
| 'x' | Signed hexadecimal (lowercase). | (2) |
| 'X' | Signed hexadecimal (uppercase). | (2) |
| 'e' | Floating point exponential format (lowercase). | (3) |
| 'E' | Floating point exponential format (uppercase). | (3) |
| 'f' | Floating point decimal format. | (3) |
| 'F' | Floating point decimal format. | (3) |
| 'g' | Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'G' | Floating point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'c' | Single character (accepts integer or single character string). | |
| 'r' | String (converts any Python object using <i>repr()</i>). | (5) |
| 's' | String (converts any Python object using <i>str()</i>). | (6) |
| '%' | No argument is converted, results in a '%' character in the result. | |

Notes:

- (1) The alternate form causes a leading zero ('0') to be inserted between left-hand padding and the formatting of the number if the leading character of the result is not already a zero.
- (2) The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.
- (3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.
The precision determines the number of digits after the decimal point and defaults to 6.
- (4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

- (5) The `%r` conversion was added in Python 2.0.

The precision determines the maximal number of characters used.

- (6) If the object or format provided is a `unicode` string, the resulting string will also be `unicode`.

The precision determines the maximal number of characters used.

- (7) See [PEP 237](#).

Since Python strings have an explicit length, `%s` conversions do not assume that `'\0'` is the end of the string.

Changed in version 2.7: `%f` conversions for numbers whose absolute value is over `1e50` are no longer replaced by `%g` conversions.

Additional string operations are defined in standard modules `string` and `re`.

5.6.3 xrange Type

The `xrange` type is an immutable sequence which is commonly used for looping. The advantage of the `xrange` type is that an `xrange` object will always take the same amount of memory, no matter the size of the range it represents. There are no consistent performance advantages.

`xrange` objects have very little behavior: they only support indexing, iteration, and the `len()` function.

5.6.4 Mutable Sequence Types

List and `bytearray` objects support additional operations that allow in-place modification of the object. Other mutable sequence types (when added to the language) should also support these operations. Strings and tuples are immutable sequence types: such objects cannot be modified once created. The following operations are defined on mutable sequence types (where `x` is an arbitrary object):

| Operation | Result | Notes |
|---|--|---------------|
| <code>s[i] = x</code> | item <i>i</i> of <i>s</i> is replaced by <i>x</i> | |
| <code>s[i:j] = t</code> | slice of <i>s</i> from <i>i</i> to <i>j</i> is replaced by the contents of the iterable <i>t</i> | |
| <code>del s[i:j]</code> | same as <code>s[i:j] = []</code> | |
| <code>s[i:j:k] = t</code> | the elements of <code>s[i:j:k]</code> are replaced by those of <i>t</i> | (1) |
| <code>del s[i:j:k]</code> | removes the elements of <code>s[i:j:k]</code> from the list | |
| <code>s.append(x)</code> | same as <code>s[len(s):len(s)] = [x]</code> | (2) |
| <code>s.extend(t)</code> or <code>s += t</code> | for the most part the same as <code>s[len(s):len(s)] = t</code> | (3) |
| <code>s *= n</code> | updates <i>s</i> with its contents repeated <i>n</i> times | (11) |
| <code>s.count(x)</code> | return number of <i>i</i> 's for which <code>s[i] == x</code> | |
| <code>s.index(x[, i[, j]])</code> | return smallest <i>k</i> such that <code>s[k] == x</code> and <code>i <= k < j</code> | (4) |
| <code>s.insert(i, x)</code> | same as <code>s[i:i] = [x]</code> | (5) |
| <code>s.pop([i])</code> | same as <code>x = s[i]; del s[i]; return x</code> | (6) |
| <code>s.remove(x)</code> | same as <code>del s[s.index(x)]</code> | (4) |
| <code>s.reverse()</code> | reverses the items of <i>s</i> in place | (7) |
| <code>s.sort([cmp[, key[, reverse]])</code> | sort the items of <i>s</i> in place | (7)(8)(9)(10) |

Notes:

- (1) *t* must have the same length as the slice it is replacing.
- (2) The C implementation of Python has historically accepted multiple parameters and implicitly joined them into a tuple; this no longer works in Python 2.0. Use of this misfeature has been deprecated since Python 1.4.
- (3) *t* can be any iterable object.
- (4) Raises `ValueError` when *x* is not found in *s*. When a negative index is passed as the second or third parameter to the `index()` method, the list length is added, as for slice indices. If it is still negative, it is truncated to zero, as for slice indices.

Changed in version 2.3: Previously, `index()` didn't have arguments for specifying start and stop positions.

- (5) When a negative index is passed as the first parameter to the `insert()` method, the list length is added, as for slice indices. If it is still negative, it is truncated to zero, as for slice indices.

Changed in version 2.3: Previously, all negative indices were truncated to zero.

- (6) The `pop()` method's optional argument *i* defaults to `-1`, so that by default the last item is removed and returned.
- (7) The `sort()` and `reverse()` methods modify the list in place for economy of space when sorting or reversing a large list. To remind you that they operate by side effect, they don't return the sorted or reversed list.
- (8) The `sort()` method takes optional arguments for controlling the comparisons.

cmp specifies a custom comparison function of two arguments (list items) which should return a negative, zero or positive number depending on whether the first argument is considered smaller than, equal to, or larger than the second argument: `cmp=lambda x,y: cmp(x.lower(), y.lower())`. The default value is `None`.

key specifies a function of one argument that is used to extract a comparison key from each list element: `key=str.lower`. The default value is `None`.

reverse is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

In general, the *key* and *reverse* conversion processes are much faster than specifying an equivalent *cmp* function. This is because *cmp* is called multiple times for each list element while *key* and *reverse* touch each element only once. Use `functools.cmp_to_key()` to convert an old-style *cmp* function to a *key* function.

Changed in version 2.3: Support for `None` as an equivalent to omitting *cmp* was added.

Changed in version 2.4: Support for *key* and *reverse* was added.

- (9) Starting with Python 2.3, the `sort()` method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).
- (10) **CPython implementation detail:** While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python 2.3 and newer makes the list appear empty for the duration, and raises `ValueError` if it can detect that the list has been mutated during a sort.
- (11) The value *n* is an integer, or an object implementing `__index__()`. Zero and negative values of *n* clear the sequence. Items in the sequence are not copied; they are referenced multiple times, as explained for `s * n` under *Sequence Types* — *str*, *unicode*, *list*, *tuple*, *bytearray*, *buffer*, *xrange*.

5.7 Set Types — `set`, `frozenset`

A *set* object is an unordered collection of distinct *hashable* objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built in *dict*, *list*, and *tuple* classes, and the *collections* module.)

New in version 2.4.

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

There are currently two built-in set types, `set` and `frozenset`. The `set` type is mutable — the contents can be changed using methods like `add()` and `remove()`. Since it is mutable, it has no hash value and cannot be used as either a dictionary key or as an element of another set. The `frozenset` type is immutable and *hashable* — its contents cannot be altered after it is created; it can therefore be used as a dictionary key or as an element of another set.

As of Python 2.7, non-empty sets (not frozensets) can be created by placing a comma-separated list of elements within braces, for example: `{'jack', 'sjoerd'}`, in addition to the `set` constructor.

The constructors for both classes work the same:

```
class set ([iterable ])
class frozenset ([iterable ])
```

Return a new set or frozenset object whose elements are taken from *iterable*. The elements of a set must be *hashable*. To represent sets of sets, the inner sets must be `frozenset` objects. If *iterable* is not specified, a new empty set is returned.

Instances of `set` and `frozenset` provide the following operations:

len(s)

Return the number of elements in set *s* (cardinality of *s*).

x in s

Test *x* for membership in *s*.

x not in s

Test *x* for non-membership in *s*.

isdisjoint(other)

Return `True` if the set has no elements in common with *other*. Sets are disjoint if and only if their intersection is the empty set.

New in version 2.6.

issubset(other)

set <= other

Test whether every element in the set is in *other*.

set < other

Test whether the set is a proper subset of *other*, that is, `set <= other` and `set != other`.

issuperset(other)

set >= other

Test whether every element in *other* is in the set.

set > other

Test whether the set is a proper superset of *other*, that is, `set >= other` and `set != other`.

union(*others)

set | other | ...

Return a new set with elements from the set and all others.

Changed in version 2.6: Accepts multiple input iterables.

intersection(*others)

set & other & ...

Return a new set with elements common to the set and all others.

Changed in version 2.6: Accepts multiple input iterables.

difference (*others)

set - other - ...

Return a new set with elements in the set that are not in the others.

Changed in version 2.6: Accepts multiple input iterables.

symmetric_difference (other)

set ^ other

Return a new set with elements in either the set or *other* but not both.

copy ()

Return a shallow copy of the set.

Note, the non-operator versions of `union()`, `intersection()`, `difference()`, and `symmetric_difference()`, `issubset()`, and `issuperset()` methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Both `set` and `frozenset` support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

Instances of `set` are compared to instances of `frozenset` based on their members. For example, `set('abc') == frozenset('abc')` returns `True` and so does `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two non-empty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a < b`, `a == b`, or `a > b`. Accordingly, sets do not implement the `__cmp__()` method.

Since sets only define partial ordering (subset relationships), the output of the `list.sort()` method is undefined for lists of sets.

Set elements, like dictionary keys, must be *hashable*.

Binary operations that mix `set` instances with `frozenset` return the type of the first operand. For example: `frozenset('ab') | set('bc')` returns an instance of `frozenset`.

The following table lists operations available for `set` that do not apply to immutable instances of `frozenset`:

update (*others)

set |= other | ...

Update the set, adding elements from all others.

Changed in version 2.6: Accepts multiple input iterables.

intersection_update (*others)

set &= other & ...

Update the set, keeping only elements found in it and all others.

Changed in version 2.6: Accepts multiple input iterables.

difference_update (*others)

set -= other | ...

Update the set, removing elements found in others.

Changed in version 2.6: Accepts multiple input iterables.

symmetric_difference_update (other)

set ^= other

Update the set, keeping only elements found in either set, but not in both.

add(*elem*)

Add element *elem* to the set.

remove(*elem*)

Remove element *elem* from the set. Raises *KeyError* if *elem* is not contained in the set.

discard(*elem*)

Remove element *elem* from the set if it is present.

pop()

Remove and return an arbitrary element from the set. Raises *KeyError* if the set is empty.

clear()

Remove all elements from the set.

Note, the non-operator versions of the *update()*, *intersection_update()*, *difference_update()*, and *symmetric_difference_update()* methods will accept any iterable as an argument.

Note, the *elem* argument to the *__contains__()*, *remove()*, and *discard()* methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

See also:

Comparison to the built-in set types Differences between the *sets* module and the built-in set types.

5.8 Mapping Types — dict

A *mapping* object maps *hashable* values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built in *list*, *set*, and *tuple* classes, and the *collections* module.)

A dictionary's keys are *almost* arbitrary values. Values that are not *hashable*, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Numeric types used for keys obey the normal rules for numeric comparison: if two numbers compare equal (such as 1 and 1.0) then they can be used interchangeably to index the same dictionary entry. (Note however, that since computers store floating-point numbers as approximations it is usually unwise to use them as dictionary keys.)

Dictionaries can be created by placing a comma-separated list of *key: value* pairs within braces, for example: {'jack': 4098, 'sjoerd': 4127} or {4098: 'jack', 4127: 'sjoerd'}, or by the *dict* constructor.

class dict(***kwarg*)

class dict(*mapping*, ***kwarg*)

class dict(*iterable*, ***kwarg*)

Return a new dictionary initialized from an optional positional argument and a possibly empty set of keyword arguments.

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it is a mapping object, a dictionary is created with the same key-value pairs as the mapping object. Otherwise, the positional argument must be an *iterable* object. Each item in the iterable must itself be an iterable with exactly two objects. The first object of each item becomes a key in the new dictionary, and the second object the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

If keyword arguments are given, the keyword arguments and their values are added to the dictionary created from the positional argument. If a key being added is already present, the value from the keyword argument replaces the value from the positional argument.

To illustrate, the following examples all return a dictionary equal to {"one": 1, "two": 2, "three": 3}:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> a == b == c == d == e
True
```

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

New in version 2.2.

Changed in version 2.3: Support for building a dictionary from keyword arguments added.

These are the operations that dictionaries support (and therefore, custom mapping types should support too):

len(d)

Return the number of items in the dictionary *d*.

d[key]

Return the item of *d* with key *key*. Raises a *KeyError* if *key* is not in the map.

If a subclass of dict defines a method `__missing__()` and *key* is not present, the *d[key]* operation calls that method with the key *key* as argument. The *d[key]* operation then returns or raises whatever is returned or raised by the `__missing__(key)` call. No other operations or methods invoke `__missing__()`. If `__missing__()` is not defined, *KeyError* is raised. `__missing__()` must be a method; it cannot be an instance variable:

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

The example above shows part of the implementation of `collections.Counter`. A different `__missing__` method is used by `collections.defaultdict`.

New in version 2.5: Recognition of `__missing__` methods of dict subclasses.

d[key] = value

Set *d[key]* to *value*.

del d[key]

Remove *d[key]* from *d*. Raises a *KeyError* if *key* is not in the map.

key in d

Return True if *d* has a key *key*, else False.

New in version 2.2.

key not in d

Equivalent to `not key in d`.

New in version 2.2.

iter(d)

Return an iterator over the keys of the dictionary. This is a shortcut for `iterkeys()`.

clear()

Remove all items from the dictionary.

copy()

Return a shallow copy of the dictionary.

fromkeys(seq[, value])

Create a new dictionary with keys from *seq* and values set to *value*.

`fromkeys()` is a class method that returns a new dictionary. *value* defaults to `None`.

New in version 2.3.

get(key[, default])

Return the value for *key* if *key* is in the dictionary, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a `KeyError`.

has_key(key)

Test for the presence of *key* in the dictionary. `has_key()` is deprecated in favor of `key in d`.

items()

Return a copy of the dictionary's list of (*key*, *value*) pairs.

CPython implementation detail: Keys and values are listed in an arbitrary order which is non-random, varies across Python implementations, and depends on the dictionary's history of insertions and deletions.

If `items()`, `keys()`, `values()`, `iteritems()`, `iterkeys()`, and `itervalues()` are called with no intervening modifications to the dictionary, the lists will directly correspond. This allows the creation of (*value*, *key*) pairs using `zip()`: `pairs = zip(d.values(), d.keys())`. The same relationship holds for the `iterkeys()` and `itervalues()` methods: `pairs = zip(d.itervalues(), d.iterkeys())` provides the same value for pairs. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.iteritems()]`.

iteritems()

Return an iterator over the dictionary's (*key*, *value*) pairs. See the note for `dict.items()`.

Using `iteritems()` while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

New in version 2.2.

iterkeys()

Return an iterator over the dictionary's keys. See the note for `dict.items()`.

Using `iterkeys()` while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

New in version 2.2.

itervalues()

Return an iterator over the dictionary's values. See the note for `dict.items()`.

Using `itervalues()` while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

New in version 2.2.

keys()

Return a copy of the dictionary's list of keys. See the note for `dict.items()`.

pop (*key* [, *default*])

If *key* is in the dictionary, remove it and return its value, else return *default*. If *default* is not given and *key* is not in the dictionary, a `KeyError` is raised.

New in version 2.3.

popitem ()

Remove and return an arbitrary (*key*, *value*) pair from the dictionary.

`popitem()` is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling `popitem()` raises a `KeyError`.

setdefault (*key* [, *default*])

If *key* is in the dictionary, return its value. If not, insert *key* with a value of *default* and return *default*. *default* defaults to `None`.

update ([*other*])

Update the dictionary with the key/value pairs from *other*, overwriting existing keys. Return `None`.

`update()` accepts either another dictionary object or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

Changed in version 2.4: Allowed the argument to be an iterable of key/value pairs and allowed keyword arguments.

values ()

Return a copy of the dictionary's list of values. See the note for `dict.items()`.

viewitems ()

Return a new view of the dictionary's items ((*key*, *value*) pairs). See below for documentation of view objects.

New in version 2.7.

viewkeys ()

Return a new view of the dictionary's keys. See below for documentation of view objects.

New in version 2.7.

viewvalues ()

Return a new view of the dictionary's values. See below for documentation of view objects.

New in version 2.7.

Dictionaries compare equal if and only if they have the same (*key*, *value*) pairs.

5.8.1 Dictionary view objects

The objects returned by `dict.viewkeys()`, `dict.viewvalues()` and `dict.viewitems()` are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Dictionary views can be iterated over to yield their respective data, and support membership tests:

len(dictview)

Return the number of entries in the dictionary.

iter(dictview)

Return an iterator over the keys, values or items (represented as tuples of (*key*, *value*)) in the dictionary.

Keys and values are iterated over in an arbitrary order which is non-random, varies across Python implementations, and depends on the dictionary's history of insertions and deletions. If keys, values and items views are iterated over with no intervening modifications to the dictionary, the order of items will directly correspond. This allows the creation of (value, key) pairs using `zip()`: `pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

Iterating views while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

x in dictview

Return `True` if `x` is in the underlying dictionary's keys, values or items (in the latter case, `x` should be a (key, value) tuple).

Keys views are set-like since their entries are unique and hashable. If all values are hashable, so that (key, value) pairs are unique and hashable, then the items view is also set-like. (Values views are not treated as set-like since the entries are generally not unique.) Then these set operations are available ("other" refers either to another view or a set):

dictview & other

Return the intersection of the dictview and the other object as a new set.

dictview | other

Return the union of the dictview and the other object as a new set.

dictview - other

Return the difference between the dictview and the other object (all elements in *dictview* that aren't in *other*) as a new set.

dictview ^ other

Return the symmetric difference (all elements either in *dictview* or *other*, but not in both) of the dictview and the other object as a new set.

An example of dictionary view usage:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.viewkeys()
>>> values = dishes.viewvalues()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
>>> print(n)
504

>>> # keys and values are iterated over in the same order
>>> list(keys)
['eggs', 'bacon', 'sausage', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['spam', 'bacon']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
```

5.9 File Objects

File objects are implemented using C's `stdio` package and can be created with the built-in `open()` function. File objects are also returned by some other built-in functions and methods, such as `os.popen()` and `os.fdopen()` and the `makefile()` method of socket objects. Temporary files can be created using the `tempfile` module, and high-level file operations such as copying, moving, and deleting files and directories can be achieved with the `shutil` module.

When a file operation fails for an I/O-related reason, the exception `IOError` is raised. This includes situations where the operation is not defined for some reason, like `seek()` on a tty device or writing a file opened for reading.

Files have the following methods:

`file.close()`

Close the file. A closed file cannot be read or written any more. Any operation which requires that the file be open will raise a `ValueError` after the file has been closed. Calling `close()` more than once is allowed.

As of Python 2.5, you can avoid having to call this method explicitly if you use the `with` statement. For example, the following code will automatically close `f` when the `with` block is exited:

```
from __future__ import with_statement # This isn't required in Python 2.6

with open("hello.txt") as f:
    for line in f:
        print line,
```

In older versions of Python, you would have needed to do this to get the same effect:

```
f = open("hello.txt")
try:
    for line in f:
        print line,
finally:
    f.close()
```

Note: Not all “file-like” types in Python support use as a context manager for the `with` statement. If your code is intended to work with any file-like object, you can use the function `contextlib.closing()` instead of using the object directly.

`file.flush()`

Flush the internal buffer, like `stdio`'s `fflush()`. This may be a no-op on some file-like objects.

Note: `flush()` does not necessarily write the file's data to disk. Use `flush()` followed by `os.fsync()` to ensure this behavior.

`file.fileno()`

Return the integer “file descriptor” that is used by the underlying implementation to request I/O operations from the operating system. This can be useful for other, lower level interfaces that use file descriptors, such as the `fcntl` module or `os.read()` and friends.

Note: File-like objects which do not have a real file descriptor should *not* provide this method!

`file.isatty()`

Return `True` if the file is connected to a tty(-like) device, else `False`.

Note: If a file-like object is not associated with a real file, this method should *not* be implemented.

`file.next()`

A file object is its own iterator, for example `iter(f)` returns `f` (unless `f` is closed). When a file is used as an iterator, typically in a `for` loop (for example, `for line in f: print line.strip()`), the `next()` method is called repeatedly. This method returns the next input line, or raises `StopIteration` when EOF is hit when the file is open for reading (behavior is undefined when the file is open for writing). In order to make a `for` loop the most efficient way of looping over the lines of a file (a very common operation), the `next()` method uses a hidden read-ahead buffer. As a consequence of using a read-ahead buffer, combining `next()` with other file methods (like `readline()`) does not work right. However, using `seek()` to reposition the file to an absolute position will flush the read-ahead buffer.

New in version 2.3.

`file.read([size])`

Read at most `size` bytes from the file (less if the read hits EOF before obtaining `size` bytes). If the `size` argument is negative or omitted, read all data until EOF is reached. The bytes are returned as a string object. An empty string is returned when EOF is encountered immediately. (For certain files, like ttys, it makes sense to continue reading after an EOF is hit.) Note that this method may call the underlying C function `fread()` more than once in an effort to acquire as close to `size` bytes as possible. Also note that when in non-blocking mode, less data than was requested may be returned, even if no `size` parameter was given.

Note: This function is simply a wrapper for the underlying `fread()` C function, and will behave the same in corner cases, such as whether the EOF value is cached.

`file.readline([size])`

Read one entire line from the file. A trailing newline character is kept in the string (but may be absent when a file ends with an incomplete line).⁶ If the `size` argument is present and non-negative, it is a maximum byte count (including the trailing newline) and an incomplete line may be returned. When `size` is not 0, an empty string is returned *only* when EOF is encountered immediately.

Note: Unlike `stdio`'s `fgets()`, the returned string contains null characters (`'\0'`) if they occurred in the input.

`file.readlines([sizehint])`

Read until EOF using `readline()` and return a list containing the lines thus read. If the optional `sizehint` argument is present, instead of reading up to EOF, whole lines totalling approximately `sizehint` bytes (possibly after rounding up to an internal buffer size) are read. Objects implementing a file-like interface may choose to ignore `sizehint` if it cannot be implemented, or cannot be implemented efficiently.

`file.xreadlines()`

This method returns the same thing as `iter(f)`.

New in version 2.1.

Deprecated since version 2.3: Use `for line in file` instead.

⁶ The advantage of leaving the newline on is that returning an empty string is then an unambiguous EOF indication. It is also possible (in cases where it might matter, for example, if you want to make an exact copy of a file while scanning its lines) to tell whether the last line of a file ended in a newline or not (yes this happens!).

`file.seek(offset[, whence])`

Set the file's current position, like `stdio's fseek()`. The *whence* argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end). There is no return value.

For example, `f.seek(2, os.SEEK_CUR)` advances the position by two and `f.seek(-3, os.SEEK_END)` sets the position to the third to last.

Note that if the file is opened for appending (mode `'a'` or `'a+'`), any *seek()* operations will be undone at the next write. If the file is only opened for writing in append mode (mode `'a'`), this method is essentially a no-op, but it remains useful for files opened in append mode with reading enabled (mode `'a+'`). If the file is opened in text mode (without `'b'`), only offsets returned by *tell()* are legal. Use of other offsets causes undefined behavior.

Note that not all file objects are seekable.

Changed in version 2.6: Passing float values as offset has been deprecated.

`file.tell()`

Return the file's current position, like `stdio's ftell()`.

Note: On Windows, *tell()* can return illegal values (after an *fgets()*) when reading files with Unix-style line-endings. Use binary mode (`'rb'`) to circumvent this problem.

`file.truncate([size])`

Truncate the file's size. If the optional *size* argument is present, the file is truncated to (at most) that size. The size defaults to the current position. The current file position is not changed. Note that if a specified size exceeds the file's current size, the result is platform-dependent: possibilities include that the file may remain unchanged, increase to the specified size as if zero-filled, or increase to the specified size with undefined new content. Availability: Windows, many Unix variants.

`file.write(str)`

Write a string to the file. There is no return value. Due to buffering, the string may not actually show up in the file until the *flush()* or *close()* method is called.

`file.writelines(sequence)`

Write a sequence of strings to the file. The sequence can be any iterable object producing strings, typically a list of strings. There is no return value. (The name is intended to match *readlines()*; *writelines()* does not add line separators.)

Files support the iterator protocol. Each iteration returns the same result as *readline()*, and iteration ends when the *readline()* method returns an empty string.

File objects also offer a number of other interesting attributes. These are not required for file-like objects, but should be implemented if they make sense for the particular object.

`file.closed`

bool indicating the current state of the file object. This is a read-only attribute; the *close()* method changes the value. It may not be available on all file-like objects.

`file.encoding`

The encoding that this file uses. When Unicode strings are written to a file, they will be converted to byte strings using this encoding. In addition, when the file is connected to a terminal, the attribute gives the encoding that the terminal is likely to use (that information might be incorrect if the user has misconfigured the terminal). The attribute is read-only and may not be present on all file-like objects. It may also be `None`, in which case the file uses the system default encoding for converting Unicode strings.

New in version 2.3.

file.errors

The Unicode error handler used along with the encoding.

New in version 2.6.

file.mode

The I/O mode for the file. If the file was created using the `open()` built-in function, this will be the value of the `mode` parameter. This is a read-only attribute and may not be present on all file-like objects.

file.name

If the file object was created using `open()`, the name of the file. Otherwise, some string that indicates the source of the file object, of the form `<...>`. This is a read-only attribute and may not be present on all file-like objects.

file.newlines

If Python was built with *universal newlines* enabled (the default) this read-only attribute exists, and for files opened in universal newline read mode it keeps track of the types of newlines encountered while reading the file. The values it can take are `'\r'`, `'\n'`, `'\r\n'`, `None` (unknown, no newlines read yet) or a tuple containing all the newline types seen, to indicate that multiple newline conventions were encountered. For files not opened in universal newlines read mode the value of this attribute will be `None`.

file.softspace

Boolean that indicates whether a space character needs to be printed before another value when using the `print` statement. Classes that are trying to simulate a file object should also have a writable `softspace` attribute, which should be initialized to zero. This will be automatic for most classes implemented in Python (care may be needed for objects that override attribute access); types implemented in C will have to provide a writable `softspace` attribute.

Note: This attribute is not used to control the `print` statement, but to allow the implementation of `print` to keep track of its internal state.

5.10 memoryview type

New in version 2.7.

`memoryview` objects allow Python code to access the internal data of an object that supports the buffer protocol without copying. Memory is generally interpreted as simple bytes.

class memoryview(obj)

Create a `memoryview` that references `obj`. `obj` must support the buffer protocol. Built-in objects that support the buffer protocol include `str` and `bytearray` (but not `unicode`).

A `memoryview` has the notion of an *element*, which is the atomic memory unit handled by the originating object `obj`. For many simple types such as `str` and `bytearray`, an element is a single byte, but other third-party types may expose larger elements.

`len(view)` returns the total number of elements in the memoryview, `view`. The `itemsize` attribute will give you the number of bytes in a single element.

A `memoryview` supports slicing to expose its data. Taking a single index will return a single element as a `str` object. Full slicing will result in a subview:

```
>>> v = memoryview('abcefg')
>>> v[1]
'b'
>>> v[-1]
```

(continues on next page)

(continued from previous page)

```
'g'
>>> v[1:4]
<memory at 0x77ab28>
>>> v[1:4].tobytes()
'bce'
```

If the object the memoryview is over supports changing its data, the memoryview supports slice assignment:

```
>>> data = bytearray('abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = 'z'
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = '123'
>>> data
bytearray(b'z123fg')
>>> v[2] = 'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot modify size of memoryview object
```

Notice how the size of the memoryview object cannot be changed.

`memoryview` has two methods:

tobytes()

Return the data in the buffer as a bytestring (an object of class `str`).

```
>>> m = memoryview("abc")
>>> m.tobytes()
'abc'
```

tolist()

Return the data in the buffer as a list of integers.

```
>>> memoryview("abc").tolist()
[97, 98, 99]
```

There are also several readonly attributes available:

format

A string containing the format (in `struct` module style) for each element in the view. This defaults to 'B', a simple bytestring.

itemsize

The size in bytes of each element of the memoryview.

shape

A tuple of integers the length of `ndim` giving the shape of the memory as an N-dimensional array.

ndim

An integer indicating how many dimensions of a multi-dimensional array the memory represents.

strides

A tuple of integers the length of `ndim` giving the size in bytes to access each element for each dimension of the array.

readonly

A bool indicating whether the memory is read only.

5.11 Context Manager Types

New in version 2.5.

Python's `with` statement supports the concept of a runtime context defined by a context manager. This is implemented using two separate methods that allow user-defined classes to define a runtime context that is entered before the statement body is executed and exited when the statement ends.

The *context management protocol* consists of a pair of methods that need to be provided for a context manager object to define a runtime context:

`contextmanager.__enter__()`

Enter the runtime context and return either this object or another object related to the runtime context. The value returned by this method is bound to the identifier in the `as` clause of `with` statements using this context manager.

An example of a context manager that returns itself is a file object. File objects return themselves from `__enter__()` to allow `open()` to be used as the context expression in a `with` statement.

An example of a context manager that returns a related object is the one returned by `decimal.localcontext()`. These managers set the active decimal context to a copy of the original decimal context and then return the copy. This allows changes to be made to the current decimal context in the body of the `with` statement without affecting code outside the `with` statement.

`contextmanager.__exit__(exc_type, exc_val, exc_tb)`

Exit the runtime context and return a Boolean flag indicating if any exception that occurred should be suppressed. If an exception occurred while executing the body of the `with` statement, the arguments contain the exception type, value and traceback information. Otherwise, all three arguments are `None`.

Returning a true value from this method will cause the `with` statement to suppress the exception and continue execution with the statement immediately following the `with` statement. Otherwise the exception continues propagating after this method has finished executing. Exceptions that occur during execution of this method will replace any exception that occurred in the body of the `with` statement.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code (such as `contextlib.nested`) to easily detect whether or not an `__exit__()` method has actually failed.

Python defines several context managers to support easy thread synchronisation, prompt closure of files or other objects, and simpler manipulation of the active decimal arithmetic context. The specific types are not treated specially beyond their implementation of the context management protocol. See the `contextlib` module for some examples.

Python's *generators* and the `contextlib.contextmanager` *decorator* provide a convenient way to implement these protocols. If a generator function is decorated with the `contextlib.contextmanager` decorator, it will return a context manager implementing the necessary `__enter__()` and `__exit__()` methods, rather than the iterator produced by an undecorated generator function.

Note that there is no specific slot for any of these methods in the type structure for Python objects in the Python/C API. Extension types wanting to define these methods must provide them as a normal Python accessible method. Compared to the overhead of setting up the runtime context, the overhead of a single class dictionary lookup is negligible.

5.12 Other Built-in Types

The interpreter supports several other kinds of objects. Most of these support only one or two operations.

5.12.1 Modules

The only special operation on a module is attribute access: `m.name`, where *m* is a module and *name* accesses a name defined in *m*'s symbol table. Module attributes can be assigned to. (Note that the `import` statement is not, strictly speaking, an operation on a module object; `import foo` does not require a module object named *foo* to exist, rather it requires an (external) *definition* for a module named *foo* somewhere.)

A special attribute of every module is `__dict__`. This is the dictionary containing the module's symbol table. Modifying this dictionary will actually change the module's symbol table, but direct assignment to the `__dict__` attribute is not possible (you can write `m.__dict__['a'] = 1`, which defines `m.a` to be 1, but you can't write `m.__dict__ = {}`). Modifying `__dict__` directly is not recommended.

Modules built into the interpreter are written like this: `<module 'sys' (built-in)>`. If loaded from a file, they are written as `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

5.12.2 Classes and Class Instances

See objects and class for these.

5.12.3 Functions

Function objects are created by function definitions. The only operation on a function object is to call it: `func(argument-list)`.

There are really two flavors of function objects: built-in functions and user-defined functions. Both support the same operation (to call the function), but the implementation is different, hence the different object types.

See function for more information.

5.12.4 Methods

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance methods. Built-in methods are described with the types that support them.

The implementation adds two special read-only attributes to class instance methods: `m.im_self` is the object on which the method operates, and `m.im_func` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.im_func(m.im_self, arg-1, arg-2, ..., arg-n)`.

Class instance methods are either *bound* or *unbound*, referring to whether the method was accessed through an instance or a class, respectively. When a method is unbound, its `im_self` attribute will be `None` and if called, an explicit `self` object must be passed as the first argument. In this case, `self` must be an instance of the unbound method's class (or a subclass of that class), otherwise a `TypeError` is raised.

Like function objects, methods objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`meth.im_func`), setting method attributes on either bound or unbound methods is disallowed. Attempting to set an attribute on a method results in an `AttributeError` being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```

>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'instancemethod' object has no attribute 'whoami'
>>> c.method.im_func.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'

```

See types for more information.

5.12.5 Code Objects

Code objects are used by the implementation to represent “pseudo-compiled” executable Python code such as a function body. They differ from function objects because they don’t contain a reference to their global execution environment. Code objects are returned by the built-in `compile()` function and can be extracted from function objects through their `func_code` attribute. See also the `code` module.

A code object can be executed or evaluated by passing it (instead of a source string) to the `exec` statement or the built-in `eval()` function.

See types for more information.

5.12.6 Type Objects

Type objects represent the various object types. An object’s type is accessed by the built-in function `type()`. There are no special operations on types. The standard module `types` defines names for all standard built-in types.

Types are written like this: `<type 'int'>`.

5.12.7 The Null Object

This object is returned by functions that don’t explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name).

It is written as `None`.

5.12.8 The Ellipsis Object

This object is used by extended slice notation (see slicings). It supports no special operations. There is exactly one ellipsis object, named `Ellipsis` (a built-in name).

It is written as `Ellipsis`. When in a subscript, it can also be written as `...`, for example `seq[...]`.

5.12.9 The NotImplemented Object

This object is returned from comparisons and binary operations when they are asked to operate on types they don’t support. See comparisons for more information.

It is written as `NotImplemented`.

5.12.10 Boolean Values

Boolean values are the two constant objects `False` and `True`. They are used to represent truth values (although other values can also be considered false or true). In numeric contexts (for example when used as the argument to an arithmetic operator), they behave like the integers 0 and 1, respectively. The built-in function `bool()` can be used to convert any value to a Boolean, if the value can be interpreted as a truth value (see section *Truth Value Testing* above).

They are written as `False` and `True`, respectively.

5.12.11 Internal Objects

See types for this information. It describes stack frame objects, traceback objects, and slice objects.

5.13 Special Attributes

The implementation adds a few special read-only attributes to several object types, where they are relevant. Some of these are not reported by the `dir()` built-in function.

`object.__dict__`

A dictionary or other mapping object used to store an object's (writable) attributes.

`object.__methods__`

Deprecated since version 2.2: Use the built-in function `dir()` to get a list of an object's attributes. This attribute is no longer available.

`object.__members__`

Deprecated since version 2.2: Use the built-in function `dir()` to get a list of an object's attributes. This attribute is no longer available.

`instance.__class__`

The class to which a class instance belongs.

`class.__bases__`

The tuple of base classes of a class object.

`definition.__name__`

The name of the class, type, function, method, descriptor, or generator instance.

The following attributes are only supported by *new-style classes*.

`class.__mro__`

This attribute is a tuple of classes that are considered when looking for base classes during method resolution.

`class.mro()`

This method can be overridden by a metaclass to customize the method resolution order for its instances. It is called at class instantiation, and its result is stored in `__mro__`.

`class.__subclasses__()`

Each new-style class keeps a list of weak references to its immediate subclasses. This method returns a list of all those references still alive. Example:

```
>>> int.__subclasses__()
[<type 'bool'>]
```

BUILT-IN EXCEPTIONS

Exceptions should be class objects. The exceptions are defined in the module `exceptions`. This module never needs to be imported explicitly: the exceptions are provided in the built-in namespace as well as the `exceptions` module.

For class exceptions, in a `try` statement with an `except` clause that mentions a particular class, that clause also handles any exception classes derived from that class (but not exception classes from which *it* is derived). Two exception classes that are not related via subclassing are never equivalent, even if they have the same name.

The built-in exceptions listed below can be generated by the interpreter or built-in functions. Except where mentioned, they have an “associated value” indicating the detailed cause of the error. This may be a string or a tuple containing several items of information (e.g., an error code and a string explaining the code). The associated value is the second argument to the `raise` statement. If the exception class is derived from the standard root class `BaseException`, the associated value is present as the exception instance’s `args` attribute.

User code can raise built-in exceptions. This can be used to test an exception handler or to report an error condition “just like” the situation in which the interpreter raises the same exception; but beware that there is nothing to prevent user code from raising an inappropriate error.

The built-in exception classes can be subclassed to define new exceptions; programmers are encouraged to derive new exceptions from the `Exception` class or one of its subclasses, and not from `BaseException`. More information on defining exceptions is available in the Python Tutorial under `tut-userexceptions`.

The following exceptions are only used as base classes for other exceptions.

exception BaseException

The base class for all built-in exceptions. It is not meant to be directly inherited by user-defined classes (for that, use `Exception`). If `str()` or `unicode()` is called on an instance of this class, the representation of the argument(s) to the instance are returned, or the empty string when there were no arguments.

New in version 2.5.

args

The tuple of arguments given to the exception constructor. Some built-in exceptions (like `IOError`) expect a certain number of arguments and assign a special meaning to the elements of this tuple, while others are usually called only with a single string giving an error message.

exception Exception

All built-in, non-system-exiting exceptions are derived from this class. All user-defined exceptions should also be derived from this class.

Changed in version 2.5: Changed to inherit from `BaseException`.

exception StandardError

The base class for all built-in exceptions except `StopIteration`, `GeneratorExit`, `KeyboardInterrupt` and `SystemExit`. `StandardError` itself is derived from `Exception`.

exception `ArithmeticError`

The base class for those built-in exceptions that are raised for various arithmetic errors: `OverflowError`, `ZeroDivisionError`, `FloatingPointError`.

exception `BufferError`

Raised when a buffer related operation cannot be performed.

exception `LookupError`

The base class for the exceptions that are raised when a key or index used on a mapping or sequence is invalid: `IndexError`, `KeyError`. This can be raised directly by `codecs.lookup()`.

exception `EnvironmentError`

The base class for exceptions that can occur outside the Python system: `IOError`, `OSError`. When exceptions of this type are created with a 2-tuple, the first item is available on the instance's `errno` attribute (it is assumed to be an error number), and the second item is available on the `strerror` attribute (it is usually the associated error message). The tuple itself is also available on the `args` attribute.

New in version 1.5.2.

When an `EnvironmentError` exception is instantiated with a 3-tuple, the first two items are available as above, while the third item is available on the `filename` attribute. However, for backwards compatibility, the `args` attribute contains only a 2-tuple of the first two constructor arguments.

The `filename` attribute is `None` when this exception is created with other than 3 arguments. The `errno` and `strerror` attributes are also `None` when the instance was created with other than 2 or 3 arguments. In this last case, `args` contains the verbatim constructor arguments as a tuple.

The following exceptions are the exceptions that are actually raised.

exception `AssertionError`

Raised when an `assert` statement fails.

exception `AttributeError`

Raised when an attribute reference (see attribute-references) or assignment fails. (When an object does not support attribute references or attribute assignments at all, `TypeError` is raised.)

exception `EOFError`

Raised when one of the built-in functions (`input()` or `raw_input()`) hits an end-of-file condition (EOF) without reading any data. (N.B.: the `file.read()` and `file.readline()` methods return an empty string when they hit EOF.)

exception `FloatingPointError`

Raised when a floating point operation fails. This exception is always defined, but can only be raised when Python is configured with the `--with-fpectl` option, or the `WANT_SIGFPE_HANDLER` symbol is defined in the `pyconfig.h` file.

exception `GeneratorExit`

Raised when a *generator's* `close()` method is called. It directly inherits from `BaseException` instead of `StandardError` since it is technically not an error.

New in version 2.5.

Changed in version 2.6: Changed to inherit from `BaseException`.

exception `IOError`

Raised when an I/O operation (such as a `print` statement, the built-in `open()` function or a method of a file object) fails for an I/O-related reason, e.g., “file not found” or “disk full”.

This class is derived from `EnvironmentError`. See the discussion above for more information on exception instance attributes.

Changed in version 2.6: Changed `socket.error` to use this as a base class.

exception ImportError

Raised when an `import` statement fails to find the module definition or when a `from ... import` fails to find a name that is to be imported.

exception IndexError

Raised when a sequence subscript is out of range. (Slice indices are silently truncated to fall in the allowed range; if an index is not a plain integer, *TypeError* is raised.)

exception KeyError

Raised when a mapping (dictionary) key is not found in the set of existing keys.

exception KeyboardInterrupt

Raised when the user hits the interrupt key (normally `Control-C` or `Delete`). During execution, a check for interrupts is made regularly. Interrupts typed when a built-in function `input()` or `raw_input()` is waiting for input also raise this exception. The exception inherits from *BaseException* so as to not be accidentally caught by code that catches *Exception* and thus prevent the interpreter from exiting.

Changed in version 2.5: Changed to inherit from *BaseException*.

exception MemoryError

Raised when an operation runs out of memory but the situation may still be rescued (by deleting some objects). The associated value is a string indicating what kind of (internal) operation ran out of memory. Note that because of the underlying memory management architecture (C's `malloc()` function), the interpreter may not always be able to completely recover from this situation; it nevertheless raises an exception so that a stack traceback can be printed, in case a run-away program was the cause.

exception NameError

Raised when a local or global name is not found. This applies only to unqualified names. The associated value is an error message that includes the name that could not be found.

exception NotImplementedError

This exception is derived from *RuntimeError*. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method.

New in version 1.5.2.

exception OSError

This exception is derived from *EnvironmentError*. It is raised when a function returns a system-related error (not for illegal argument types or other incidental errors). The `errno` attribute is a numeric error code from `errno`, and the `strerror` attribute is the corresponding string, as would be printed by the C function `perror()`. See the module *errno*, which contains names for the error codes defined by the underlying operating system.

For exceptions that involve a file system path (such as `chdir()` or `unlink()`), the exception instance will contain a third attribute, `filename`, which is the file name passed to the function.

New in version 1.5.2.

exception OverflowError

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for long integers (which would rather raise *MemoryError* than give up) and for most operations with plain integers, which return a long integer instead. Because of the lack of standardization of floating point exception handling in C, most floating point operations also aren't checked.

exception ReferenceError

This exception is raised when a weak reference proxy, created by the `weakref.proxy()` function, is used to access an attribute of the referent after it has been garbage collected. For more information on weak references, see the *weakref* module.

New in version 2.2: Previously known as the *weakref.ReferenceError* exception.

exception `RuntimeError`

Raised when an error is detected that doesn't fall in any of the other categories. The associated value is a string indicating what precisely went wrong.

exception `StopIteration`

Raised by an *iterator's* `next()` method to signal that there are no further values. This is derived from *Exception* rather than *StandardError*, since this is not considered an error in its normal application.

New in version 2.2.

exception `SyntaxError`

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in an `exec` statement, in a call to the built-in function `eval()` or `input()`, or when reading the initial script or standard input (also interactively).

Instances of this class have attributes `filename`, `lineno`, `offset` and `text` for easier access to the details. `str()` of the exception instance returns only the message.

exception `IndentationError`

Base class for syntax errors related to incorrect indentation. This is a subclass of *SyntaxError*.

exception `TabError`

Raised when indentation contains an inconsistent use of tabs and spaces. This is a subclass of *IndentationError*.

exception `SystemError`

Raised when the interpreter finds an internal error, but the situation does not look so serious to cause it to abandon all hope. The associated value is a string indicating what went wrong (in low-level terms).

You should report this to the author or maintainer of your Python interpreter. Be sure to report the version of the Python interpreter (`sys.version`; it is also printed at the start of an interactive Python session), the exact error message (the exception's associated value) and if possible the source of the program that triggered the error.

exception `SystemExit`

This exception is raised by the `sys.exit()` function. When it is not handled, the Python interpreter exits; no stack traceback is printed. If the associated value is a plain integer, it specifies the system exit status (passed to C's `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object's value is printed and the exit status is one.

Instances have an attribute `code` which is set to the proposed exit status or error message (defaulting to `None`). Also, this exception derives directly from *BaseException* and not *StandardError*, since it is not technically an error.

A call to `sys.exit()` is translated into an exception so that clean-up handlers (`finally` clauses of `try` statements) can be executed, and so that a debugger can execute a script without running the risk of losing control. The `os._exit()` function can be used if it is absolutely positively necessary to exit immediately (for example, in the child process after a call to `os.fork()`).

The exception inherits from *BaseException* instead of *StandardError* or *Exception* so that it is not accidentally caught by code that catches *Exception*. This allows the exception to properly propagate up and cause the interpreter to exit.

Changed in version 2.5: Changed to inherit from *BaseException*.

exception `TypeError`

Raised when an operation or function is applied to an object of inappropriate type. The associated value is a string giving details about the type mismatch.

exception `UnboundLocalError`

Raised when a reference is made to a local variable in a function or method, but no value has been bound to that variable. This is a subclass of *NameError*.

New in version 2.0.

exception UnicodeError

Raised when a Unicode-related encoding or decoding error occurs. It is a subclass of *ValueError*.

UnicodeError has attributes that describe the encoding or decoding error. For example, `err.object[err.start:err.end]` gives the particular invalid input that the codec failed on.

encoding

The name of the encoding that raised the error.

reason

A string describing the specific codec error.

object

The object the codec was attempting to encode or decode.

start

The first index of invalid data in *object*.

end

The index after the last invalid data in *object*.

New in version 2.0.

exception UnicodeEncodeError

Raised when a Unicode-related error occurs during encoding. It is a subclass of *UnicodeError*.

New in version 2.3.

exception UnicodeDecodeError

Raised when a Unicode-related error occurs during decoding. It is a subclass of *UnicodeError*.

New in version 2.3.

exception UnicodeTranslateError

Raised when a Unicode-related error occurs during translating. It is a subclass of *UnicodeError*.

New in version 2.3.

exception ValueError

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as *IndexError*.

exception VMSError

Only available on VMS. Raised when a VMS-specific error occurs.

exception WindowsError

Raised when a Windows-specific error occurs or when the error number does not correspond to an `errno` value. The `winerror` and `strerror` values are created from the return values of the `GetLastError()` and `FormatMessage()` functions from the Windows Platform API. The `errno` value maps the `winerror` value to corresponding `errno.h` values. This is a subclass of *OSError*.

New in version 2.0.

Changed in version 2.5: Previous versions put the `GetLastError()` codes into `errno`.

exception ZeroDivisionError

Raised when the second argument of a division or modulo operation is zero. The associated value is a string indicating the type of the operands and the operation.

The following exceptions are used as warning categories; see the *warnings* module for more information.

exception Warning

Base class for warning categories.

exception UserWarning

Base class for warnings generated by user code.

exception DeprecationWarning

Base class for warnings about deprecated features.

exception PendingDeprecationWarning

Base class for warnings about features which will be deprecated in the future.

exception SyntaxWarning

Base class for warnings about dubious syntax.

exception RuntimeWarning

Base class for warnings about dubious runtime behavior.

exception FutureWarning

Base class for warnings about constructs that will change semantically in the future.

exception ImportError

Base class for warnings about probable mistakes in module imports.

New in version 2.5.

exception UnicodeWarning

Base class for warnings related to Unicode.

New in version 2.5.

exception BytesWarning

Base class for warnings related to bytes and bytearray.

New in version 2.6.

6.1 Exception hierarchy

The class hierarchy for built-in exceptions is:

```
BaseException
+-- SystemExit
+-- KeyboardInterrupt
+-- GeneratorExit
+-- Exception
    +-- StopIteration
    +-- StandardError
        | +-- BufferError
        | +-- ArithmeticError
        | | +-- FloatingPointError
        | | +-- OverflowError
        | | +-- ZeroDivisionError
        | +-- AssertionError
        | +-- AttributeError
        | +-- EnvironmentError
        | | +-- IOError
        | | +-- OSError
        | | +-- WindowsError (Windows)
        | | +-- VMSError (VMS)
        | +-- EOFError
        | +-- ImportError
        | +-- LookupError
```

(continues on next page)

(continued from previous page)

```
| | +-- IndexError
| | +-- KeyError
| +-- MemoryError
| +-- NameError

    +-- BytesWarning
```

STRING SERVICES

The modules described in this chapter provide a wide range of string manipulation operations.

In addition, Python's built-in string classes support the sequence type methods described in the *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* section, and also the string-specific methods described in the *String Methods* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. Also, see the *re* module for string functions based on regular expressions.

7.1 string — Common string operations

Source code: [Lib/string.py](#)

The *string* module contains a number of useful constants and classes, as well as some deprecated legacy functions that are also available as methods on strings. In addition, Python's built-in string classes support the sequence type methods described in the *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* section, and also the string-specific methods described in the *String Methods* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. Also, see the *re* module for string functions based on regular expressions.

7.1.1 String constants

The constants defined in this module are:

`string.ascii_letters`

The concatenation of the *ascii_lowercase* and *ascii_uppercase* constants described below. This value is not locale-dependent.

`string.ascii_lowercase`

The lowercase letters 'abcdefghijklmnopqrstuvwxyz'. This value is not locale-dependent and will not change.

`string.ascii_uppercase`

The uppercase letters 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'. This value is not locale-dependent and will not change.

`string.digits`

The string '0123456789'.

`string.hexdigits`

The string '0123456789abcdefABCDEF'.

string.letters

The concatenation of the strings *lowercase* and *uppercase* described below. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

string.lowercase

A string containing all the characters that are considered lowercase letters. On most systems this is the string 'abcdefghijklmnopqrstuvwxyz'. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

string.octdigits

The string '01234567'.

string.punctuation

String of ASCII characters which are considered punctuation characters in the C locale.

string.printable

String of characters which are considered printable. This is a combination of *digits*, *letters*, *punctuation*, and *whitespace*.

string.uppercase

A string containing all the characters that are considered uppercase letters. On most systems this is the string 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

string.whitespace

A string containing all characters that are considered whitespace. On most systems this includes the characters space, tab, linefeed, return, formfeed, and vertical tab.

7.1.2 Custom String Formatting

New in version 2.6.

The built-in str and unicode classes provide the ability to do complex variable substitutions and value formatting via the *str.format()* method described in [PEP 3101](#). The *Formatter* class in the *string* module allows you to create and customize your own string formatting behaviors using the same implementation as the built-in *format()* method.

class string.Formatter

The *Formatter* class has the following public methods:

format (*format_string*, **args*, ***kwargs*)

The primary API method. It takes a format string and an arbitrary set of positional and keyword arguments. It is just a wrapper that calls *vformat()*.

vformat (*format_string*, *args*, *kwargs*)

This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the **args* and ***kwargs* syntax. *vformat()* does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the *Formatter* defines a number of methods that are intended to be replaced by subclasses:

parse (*format_string*)

Loop over the *format_string* and return an iterable of tuples (*literal_text*, *field_name*, *format_spec*, *conversion*). This is used by *vformat()* to break the string into either literal text, or replacement fields.

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then *literal_text* will be a zero-length string. If there is no replacement field, then the values of *field_name*, *format_spec* and *conversion* will be None.

get_field (*field_name*, *args*, *kwargs*)

Given *field_name* as returned by `parse()` (see above), convert it to an object to be formatted. Returns a tuple (obj, used_key). The default version takes strings of the form defined in [PEP 3101](#), such as “0[name]” or “label.title”. *args* and *kwargs* are as passed in to `vformat()`. The return value *used_key* has the same meaning as the *key* parameter to `get_value()`.

get_value (*key*, *args*, *kwargs*)

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to `vformat()`, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; Subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression ‘0.name’ would cause `get_value()` to be called with a *key* argument of 0. The `name` attribute will be looked up after `get_value()` returns by calling the built-in `getattr()` function.

If the index or keyword refers to an item that does not exist, then an `IndexError` or `KeyError` should be raised.

check_unused_args (*used_args*, *args*, *kwargs*)

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to `vformat`. The set of unused args can be calculated from these parameters. `check_unused_args()` is assumed to raise an exception if the check fails.

format_field (*value*, *format_spec*)

`format_field()` simply calls the global `format()` built-in. The method is provided so that subclasses can override it.

convert_field (*value*, *conversion*)

Converts the value (returned by `get_field()`) given a conversion type (as in the tuple returned by the `parse()` method). The default version understands ‘s’ (str), ‘r’ (repr) and ‘a’ (ascii) conversion types.

7.1.3 Format String Syntax

The `str.format()` method and the `Formatter` class share the same syntax for format strings (although in the case of `Formatter`, subclasses can define their own format string syntax).

Format strings contain “replacement fields” surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name         ::= arg_name ("." attribute_name | "[" element_index "]") *
arg_name           ::= [identifier | integer]
attribute_name     ::= identifier
element_index      ::= integer | index_string
index_string       ::= <any source character except "]"> +
conversion         ::= "r" | "s"
```

```
format_spec ::= <described in the next section>
```

In less formal terms, the replacement field can start with a *field_name* that specifies the object whose value is to be formatted and inserted into the output instead of the replacement field. The *field_name* is optionally followed by a *conversion* field, which is preceded by an exclamation point '!', and a *format_spec*, which is preceded by a colon ':'. These specify a non-default format for the replacement value.

See also the *Format Specification Mini-Language* section.

The *field_name* itself begins with an *arg_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. If the numerical *arg_names* in a format string are 0, 1, 2, ... in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, ... will be automatically inserted in that order. Because *arg_name* is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings '10' or ':-]') within a format string. The *arg_name* can be followed by any number of index or attribute expressions. An expression of the form '.name' selects the named attribute using *getattr()*, while an expression of the form '[index]' does an index lookup using *__getitem__()*.

Changed in version 2.7: The positional argument specifiers can be omitted for *str.format()* and *unicode.format()*, so '{ } { }' is equivalent to '{0} {1}', *u'{ } { }'* is equivalent to *u'{0} {1}'*.

Some simple format string examples:

```
"First, thou shalt count to {0}" # References first positional argument
"Bring me a {}"                 # Implicitly references the first positional_
                                ↪ argument
"From {} to {}"                 # Same as "From {0} to {1}"
"My quest is {name}"            # References keyword argument 'name'
"Weight in tons {0.weight}"     # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}" # First element of keyword argument 'players'.
```

The *conversion* field causes a type coercion before formatting. Normally, the job of formatting a value is done by the *__format__()* method of the value itself. However, in some cases it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling *__format__()*, the normal formatting logic is bypassed.

Two conversion flags are currently supported: '!s' which calls *str()* on the value, and '!r' which calls *repr()*.

Some examples:

```
"Harold's a clever {0!s}"       # Calls str() on the argument first
"Bring out the holy {name!r}"   # Calls repr() on the argument first
```

The *format_spec* field contains a specification of how the value should be presented, including such details as field width, alignment, padding, decimal precision and so on. Each value type can define its own “formatting mini-language” or interpretation of the *format_spec*.

Most built-in types support a common formatting mini-language, which is described in the next section.

A *format_spec* field can also include nested replacement fields within it. These nested replacement fields may contain a field name, conversion flag and format specification, but deeper nesting is not allowed. The replacement fields within the *format_spec* are substituted before the *format_spec* string is interpreted. This allows the formatting of a value to be dynamically specified.

See the *Format examples* section for some examples.

Format Specification Mini-Language

“Format specifications” are used within replacement fields contained within a format string to define how individual values are presented (see *Format String Syntax*). They can also be passed directly to the built-in *format()* function. Each

formattable type may define how the format specification is to be interpreted.

Most built-in types implement the following options for format specifications, although some of the formatting options are only supported by the numeric types.

A general convention is that an empty format string ("") produces the same result as if you had called `str()` on the value. A non-empty format string typically modifies the result.

The general form of a *standard format specifier* is:

```
format_spec ::= [[fill]align][sign][#][0][width][,][.precision][type]
fill        ::= <any character>
align       ::= "<" | ">" | "=" | "^"
sign        ::= "+" | "-" | " "
width       ::= integer
precision   ::= integer
type        ::= "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s" |
```

If a valid *align* value is specified, it can be preceded by a *fill* character that can be any character and defaults to a space if omitted. It is not possible to use a literal curly brace (“{” or “}”) as the *fill* character when using the `str.format()` method. However, it is possible to insert a curly brace with a nested replacement field. This limitation doesn’t affect the `format()` function.

The meaning of the various alignment options is as follows:

| Op- tion | Meaning |
|-------------|--|
| '<' | Forces the field to be left-aligned within the available space (this is the default for most objects). |
| '>' | Forces the field to be right-aligned within the available space (this is the default for numbers). |
| '=' | Forces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form ‘+000000120’. This alignment option is only valid for numeric types. It becomes the default when ‘0’ immediately precedes the field width. |
| '^' | Forces the field to be centered within the available space. |

Note that unless a minimum field width is defined, the field width will always be the same size as the data to fill it, so that the alignment option has no meaning in this case.

The *sign* option is only valid for number types, and can be one of the following:

| Op- tion | Meaning |
|-------------|--|
| '+' | indicates that a sign should be used for both positive as well as negative numbers. |
| '-' | indicates that a sign should be used only for negative numbers (this is the default behavior). |
| space | indicates that a leading space should be used on positive numbers, and a minus sign on negative numbers. |

The '#' option is only valid for integers, and only for binary, octal, or hexadecimal output. If present, it specifies that the output will be prefixed by '0b', '0o', or '0x', respectively.

The ',' option signals the use of a comma for a thousands separator. For a locale aware separator, use the 'n' integer presentation type instead.

Changed in version 2.7: Added the ',' option (see also [PEP 378](#)).

width is a decimal integer defining the minimum field width. If not specified, then the field width will be determined by the content.

When no explicit alignment is given, preceding the *width* field by a zero ('0') character enables sign-aware zero-padding for numeric types. This is equivalent to a *fill* character of '0' with an *alignment* type of '='.

The *precision* is a decimal number indicating how many digits should be displayed after the decimal point for a floating point value formatted with 'f' and 'F', or before and after the decimal point for a floating point value formatted with 'g' or 'G'. For non-number types the field indicates the maximum field size - in other words, how many characters will be used from the field content. The *precision* is not allowed for integer values.

Finally, the *type* determines how the data should be presented.

The available string presentation types are:

| Type | Meaning |
|------|---|
| 's' | String format. This is the default type for strings and may be omitted. |
| None | The same as 's'. |

The available integer presentation types are:

| Type | Meaning |
|------|--|
| 'b' | Binary format. Outputs the number in base 2. |
| 'c' | Character. Converts the integer to the corresponding unicode character before printing. |
| 'd' | Decimal Integer. Outputs the number in base 10. |
| 'o' | Octal format. Outputs the number in base 8. |
| 'x' | Hex format. Outputs the number in base 16, using lower- case letters for the digits above 9. |
| 'X' | Hex format. Outputs the number in base 16, using upper- case letters for the digits above 9. |
| 'n' | Number. This is the same as 'd', except that it uses the current locale setting to insert the appropriate number separator characters. |
| None | The same as 'd'. |

In addition to the above presentation types, integers can be formatted with the floating point presentation types listed below (except 'n' and None). When doing so, `float()` is used to convert the integer to a floating point number before formatting.

The available presentation types for floating point and decimal values are:

| Type | Meaning |
|------|--|
| 'e' | Exponent notation. Prints the number in scientific notation using the letter 'e' to indicate the exponent. The default precision is 6. |
| 'E' | Exponent notation. Same as 'e' except it uses an upper case 'E' as the separator character. |
| 'f' | Fixed-point notation. Displays the number as a fixed-point number. The default precision is 6. |
| 'F' | Fixed point notation. Same as 'f'. |
| 'g' | General format. For a given precision $p \geq 1$, this rounds the number to p significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. The precise rules are as follows: suppose that the result formatted with presentation type 'e' and precision $p-1$ would have exponent exp . Then if $-4 \leq exp < p$, the number is formatted with presentation type 'f' and precision $p-1-exp$. Otherwise, the number is formatted with presentation type 'e' and precision $p-1$. In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it. Positive and negative infinity, positive and negative zero, and nans, are formatted as <code>inf</code> , <code>-inf</code> , <code>0</code> , <code>-0</code> and <code>nan</code> respectively, regardless of the precision. A precision of 0 is treated as equivalent to a precision of 1. The default precision is 6. |
| 'G' | General format. Same as 'g' except switches to 'E' if the number gets too large. The representations of infinity and NaN are uppercased, too. |
| 'n' | Number. This is the same as 'g', except that it uses the current locale setting to insert the appropriate number separator characters. |
| '%' | Percentage. Multiplies the number by 100 and displays in fixed ('f') format, followed by a percent sign. |
| None | The same as 'g'. |

Format examples

This section contains examples of the `str.format()` syntax and comparison with the old %-formatting.

In most of the cases the syntax is similar to the old %-formatting, with the addition of the `{}` and with `:` used instead of `%`. For example, `'%03.2f'` can be translated to `'{:03.2f}'`.

The new format syntax also supports new and different options, shown in the following examples.

Accessing arguments by position:

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c')    # 2.7+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')         # unpacking argument sequence
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad')     # arguments' indices can be repeated
'abracadabra'
```

Accessing arguments by name:

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.
↳ 81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
```

(continues on next page)

(continued from previous page)

```
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

Accessing arguments' attributes:

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
... 'and the imaginary part {0.imag}.'.format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.
↪0.'
```

```
>>> class Point(object):
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

Accessing arguments' items:

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

Replacing %s and %r:

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
'repr() shows quotes: 'test1'; str() doesn't: test2'
```

Aligning the text and specifying a width:

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:^30}'.format('centered')
'centered'
>>> '{:*^30}'.format('centered') # use '*' as a fill char
'*****centered*****'
```

Replacing %f, %-f, and % f and specifying a sign:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14) # show it always
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14) # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {-f}'.format(3.14, -3.14) # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

Replacing %x and %o and converting the value to different bases:

```
>>> # format also supports binary numbers
>>> "int: {0:d}; hex: {0:x}; oct: {0:o}; bin: {0:b}".format(42)
'int: 42; hex: 2a; oct: 52; bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
```

(continues on next page)

(continued from previous page)

```
>>> "int: {0:d};  hex: {0:#x};  oct: {0:#o};  bin: {0:#b}".format(42)
'int: 42;  hex: 0x2a;  oct: 0o52;  bin: 0b101010'
```

Using the comma as a thousands separator:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

Expressing a percentage:

```
>>> points = 19.5
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 88.64%'
```

Using type-specific formatting:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

Nesting arguments and more complex examples:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
'left<<<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print '{0:{width}{base}}'.format(num, base=base, width=width),
...     print
...
5      5      5      101
6      6      6      110
7      7      7      111
8      8      10     1000
9      9      11     1001
10     A      12     1010
11     B      13     1011
```

7.1.4 Template strings

New in version 2.4.

Templates provide simpler string substitutions as described in [PEP 292](#). Instead of the normal %-based substitutions, Templates support \$-based substitutions, using the following rules:

- `$$` is an escape; it is replaced with a single `$`.
- `$identifier` names a substitution placeholder matching a mapping key of `"identifier"`. By default, `"identifier"` must spell a Python identifier. The first non-identifier character after the `$` character terminates this placeholder specification.
- `${identifier}` is equivalent to `$identifier`. It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as `"${noun}ification"`.

Any other appearance of `$` in the string will result in a `ValueError` being raised.

The `string` module provides a `Template` class that implements these rules. The methods of `Template` are:

class `string.Template(template)`

The constructor takes a single argument which is the template string.

substitute(mapping[, **kws])

Performs the template substitution, returning a new string. *mapping* is any dictionary-like object with keys that match the placeholders in the template. Alternatively, you can provide keyword arguments, where the keywords are the placeholders. When both *mapping* and *kws* are given and there are duplicates, the placeholders from *kws* take precedence.

safe_substitute(mapping[, **kws])

Like `substitute()`, except that if placeholders are missing from *mapping* and *kws*, instead of raising a `KeyError` exception, the original placeholder will appear in the resulting string intact. Also, unlike with `substitute()`, any other appearances of the `$` will simply return `$` instead of raising `ValueError`.

While other exceptions may still occur, this method is called “safe” because it always tries to return a usable string instead of raising an exception. In another sense, `safe_substitute()` may be anything other than safe, since it will silently ignore malformed templates containing dangling delimiters, unmatched braces, or placeholders that are not valid Python identifiers.

`Template` instances also provide one public data attribute:

template

This is the object passed to the constructor’s *template* argument. In general, you shouldn’t change it, but read-only access is not enforced.

Here is an example of how to use a `Template`:

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

Advanced usage: you can derive subclasses of `Template` to customize the placeholder syntax, delimiter character, or the entire regular expression used to parse template strings. To do this, you can override these class attributes:

- *delimiter* – This is the literal string describing a placeholder introducing delimiter. The default value is `$`. Note that this should *not* be a regular expression, as the implementation will call `re.escape()` on this string as needed.
- *idpattern* – This is the regular expression describing the pattern for non-braced placeholders (the braces will be added automatically as appropriate). The default value is the regular expression `[_a-z][_a-z0-9]*`.

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* – This group matches the escape sequence, e.g. `$$`, in the default pattern.
- *named* – This group matches the unbraced placeholder name; it should not include the delimiter in capturing group.
- *braced* – This group matches the brace enclosed placeholder name; it should not include either the delimiter or braces in the capturing group.
- *invalid* – This group matches any other delimiter pattern (usually a single delimiter), and it should appear last in the regular expression.

7.1.5 String functions

The following functions are available to operate on string and Unicode objects. They are not available as string methods.

`string.capwords(s[, sep])`

Split the argument into words using `str.split()`, capitalize each word using `str.capitalize()`, and join the capitalized words using `str.join()`. If the optional second argument *sep* is absent or `None`, runs of whitespace characters are replaced by a single space and leading and trailing whitespace are removed, otherwise *sep* is used to split and join the words.

`string.maketrans(from, to)`

Return a translation table suitable for passing to `translate()`, that will map each character in *from* into the character at the same position in *to*; *from* and *to* must have the same length.

Note: Don't use strings derived from `lowercase` and `uppercase` as arguments; in some locales, these don't have the same length. For case conversions, always use `str.lower()` and `str.upper()`.

7.1.6 Deprecated string functions

The following list of functions are also defined as methods of string and Unicode objects; see section *String Methods* for more information on those. You should consider these functions as deprecated, although they will not be removed until Python 3. The functions defined in this module are:

`string.atof(s)`

Deprecated since version 2.0: Use the `float()` built-in function.

Convert a string to a floating point number. The string must have the standard syntax for a floating point literal in Python, optionally preceded by a sign (+ or -). Note that this behaves identical to the built-in function `float()` when passed a string.

Note: When passing in a string, values for NaN and Infinity may be returned, depending on the underlying C library. The specific set of strings accepted which cause these values to be returned depends entirely on the C library and is known to vary.

`string.atoi(s[, base])`

Deprecated since version 2.0: Use the `int()` built-in function.

Convert string *s* to an integer in the given *base*. The string must consist of one or more digits, optionally preceded by a sign (+ or -). The *base* defaults to 10. If it is 0, a default base is chosen depending on the leading characters of the string (after stripping the sign): 0x or 0X means 16, 0 means 8, anything else means 10. If *base* is 16, a leading 0x or 0X is always accepted, though not required. This behaves identically to the built-in function `int()` when passed a string. (Also note: for a more flexible interpretation of numeric literals, use the built-in function `eval()`.)

`string.atol(s[, base])`

Deprecated since version 2.0: Use the `long()` built-in function.

Convert string *s* to a long integer in the given *base*. The string must consist of one or more digits, optionally preceded by a sign (+ or -). The *base* argument has the same meaning as for `atoi()`. A trailing l or L is not allowed, except if the base is 0. Note that when invoked without *base* or with *base* set to 10, this behaves identical to the built-in function `long()` when passed a string.

`string.capitalize(word)`

Return a copy of *word* with only its first character capitalized.

`string.expandtabs(s[, tabsize])`

Expand tabs in a string replacing them by one or more spaces, depending on the current column and the given tab size. The column number is reset to zero after each newline occurring in the string. This doesn't understand other non-printing characters or escape sequences. The tab size defaults to 8.

`string.find(s, sub[, start[, end]])`

Return the lowest index in *s* where the substring *sub* is found such that *sub* is wholly contained in *s*[*start*:*end*]. Return -1 on failure. Defaults for *start* and *end* and interpretation of negative values is the same as for slices.

`string.rfind(s, sub[, start[, end]])`

Like `find()` but find the highest index.

`string.index(s, sub[, start[, end]])`

Like `find()` but raise `ValueError` when the substring is not found.

`string.rindex(s, sub[, start[, end]])`

Like `rfind()` but raise `ValueError` when the substring is not found.

`string.count(s, sub[, start[, end]])`

Return the number of (non-overlapping) occurrences of substring *sub* in string *s*[*start*:*end*]. Defaults for *start* and *end* and interpretation of negative values are the same as for slices.

`string.lower(s)`

Return a copy of *s*, but with upper case letters converted to lower case.

`string.split(s[, sep[, maxsplit]])`

Return a list of the words of the string *s*. If the optional second argument *sep* is absent or `None`, the words are separated by arbitrary strings of whitespace characters (space, tab, newline, return, formfeed). If the second argument *sep* is present and not `None`, it specifies a string to be used as the word separator. The returned list will then have one more item than the number of non-overlapping occurrences of the separator in the string. If *maxsplit* is given, at most *maxsplit* number of splits occur, and the remainder of the string is returned as the final element of the list (thus, the list will have at most *maxsplit*+1 elements). If *maxsplit* is not specified or -1, then there is no limit on the number of splits (all possible splits are made).

The behavior of `split` on an empty string depends on the value of *sep*. If *sep* is not specified, or specified as `None`, the result will be an empty list. If *sep* is specified as any string, the result will be a list containing one element which is an empty string.

`string.rsplit(s[, sep[, maxsplit]])`

Return a list of the words of the string *s*, scanning *s* from the end. To all intents and purposes, the resulting list of

words is the same as returned by `split()`, except when the optional third argument `maxsplit` is explicitly specified and nonzero. If `maxsplit` is given, at most `maxsplit` number of splits – the *rightmost* ones – occur, and the remainder of the string is returned as the first element of the list (thus, the list will have at most `maxsplit+1` elements).

New in version 2.4.

`string.splitfields(s[, sep[, maxsplit]])`

This function behaves identically to `split()`. (In the past, `split()` was only used with one argument, while `splitfields()` was only used with two arguments.)

`string.join(words[, sep])`

Concatenate a list or tuple of words with intervening occurrences of `sep`. The default value for `sep` is a single space character. It is always true that `string.join(string.split(s, sep), sep)` equals `s`.

`string.joinfields(words[, sep])`

This function behaves identically to `join()`. (In the past, `join()` was only used with one argument, while `joinfields()` was only used with two arguments.) Note that there is no `joinfields()` method on string objects; use the `join()` method instead.

`string.lstrip(s[, chars])`

Return a copy of the string with leading characters removed. If `chars` is omitted or `None`, whitespace characters are removed. If given and not `None`, `chars` must be a string; the characters in the string will be stripped from the beginning of the string this method is called on.

Changed in version 2.2.3: The `chars` parameter was added. The `chars` parameter cannot be passed in earlier 2.2 versions.

`string.rstrip(s[, chars])`

Return a copy of the string with trailing characters removed. If `chars` is omitted or `None`, whitespace characters are removed. If given and not `None`, `chars` must be a string; the characters in the string will be stripped from the end of the string this method is called on.

Changed in version 2.2.3: The `chars` parameter was added. The `chars` parameter cannot be passed in earlier 2.2 versions.

`string.strip(s[, chars])`

Return a copy of the string with leading and trailing characters removed. If `chars` is omitted or `None`, whitespace characters are removed. If given and not `None`, `chars` must be a string; the characters in the string will be stripped from the both ends of the string this method is called on.

Changed in version 2.2.3: The `chars` parameter was added. The `chars` parameter cannot be passed in earlier 2.2 versions.

`string.swapcase(s)`

Return a copy of `s`, but with lower case letters converted to upper case and vice versa.

`string.translate(s, table[, deletechars])`

Delete all characters from `s` that are in `deletechars` (if present), and then translate the characters using `table`, which must be a 256-character string giving the translation for each character value, indexed by its ordinal. If `table` is `None`, then only the character deletion step is performed.

`string.upper(s)`

Return a copy of `s`, but with lower case letters converted to upper case.

`string.ljust(s, width[, fillchar])`

`string.rjust(s, width[, fillchar])`

`string.center(s, width[, fillchar])`

These functions respectively left-justify, right-justify and center a string in a field of given width. They return a string that is at least `width` characters wide, created by padding the string `s` with the character `fillchar` (default is a space) until the given width on the right, left or both sides. The string is never truncated.

`string.zfill(s, width)`

Pad a numeric string *s* on the left with zero digits until the given *width* is reached. Strings starting with a sign are handled correctly.

`string.replace(s, old, new[, maxreplace])`

Return a copy of string *s* with all occurrences of substring *old* replaced by *new*. If the optional argument *maxreplace* is given, the first *maxreplace* occurrences are replaced.

7.2 re — Regular expression operations

This module provides regular expression matching operations similar to those found in Perl. Both patterns and strings to be searched can be Unicode strings as well as 8-bit strings.

Regular expressions use the backslash character ('\\') to indicate special forms or to allow special characters to be used without invoking their special meaning. This collides with Python's usage of the same character for the same purpose in string literals; for example, to match a literal backslash, one might have to write '\\\\' as the pattern string, because the regular expression must be \\, and each backslash must be expressed as \\ inside a regular Python string literal.

The solution is to use Python's raw string notation for regular expression patterns; backslashes are not handled in any special way in a string literal prefixed with 'r'. So `r"\n"` is a two-character string containing '\\' and 'n', while `"\n"` is a one-character string containing a newline. Usually patterns will be expressed in Python code using this raw string notation.

It is important to note that most regular expression operations are available as module-level functions and *RegexObject* methods. The functions are shortcuts that don't require you to compile a regex object first, but miss some fine-tuning parameters.

See also:

The third-party *regex* module, which has an API compatible with the standard library *re* module, but offers additional functionality and a more thorough Unicode support.

7.2.1 Regular Expression Syntax

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match *AB*. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book referenced above, or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the *regex-howto*.

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like 'A', 'a', or '0', are the simplest regular expressions; they simply match themselves. You can concatenate ordinary characters, so `last` matches the string 'last'. (In the rest of this section, we'll write RE's in this special style, usually without quotes, and strings to be matched 'in single quotes'.)

Some characters, like '|' or '(', are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted. Regular expression pattern strings may not contain null bytes, but can specify the null byte using the `\number` notation, e.g., `'\x00'`.

Repetition qualifiers (`*`, `+`, `?`, `{m, n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six 'a' characters.

The special characters are:

- '.' (Dot.) In the default mode, this matches any character except a newline. If the `DOTALL` flag has been specified, this matches any character including a newline.
- '^' (Caret.) Matches the start of the string, and in `MULTILINE` mode also matches immediately after each newline.
- '\$' Matches the end of the string or just before the newline at the end of the string, and in `MULTILINE` mode also matches before a newline. `foo` matches both 'foo' and 'foobar', while the regular expression `foo$` matches only 'foo'. More interestingly, searching for `foo.$` in `'foo1\nfoo2\n'` matches 'foo2' normally, but 'foo1' in `MULTILINE` mode; searching for a single `$` in `'foo\n'` will find two (empty) matches: one just before the newline, and one at the end of the string.
- '*' Causes the resulting RE to match 0 or more repetitions of the preceding RE, as many repetitions as are possible. `ab*` will match 'a', 'ab', or 'a' followed by any number of 'b's.
- '+' Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match 'a' followed by any non-zero number of 'b's; it will not match just 'a'.
- '?' Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either 'a' or 'ab'.
- `*, +, ?` The `'*'`, `'+'`, and `'?'` qualifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against `<a> b <c>`, it will match the entire string, and not just `<a>`. Adding `?` after the qualifier makes it perform the match in *non-greedy* or *minimal* fashion; as few characters as possible will be matched. Using the RE `<.*?>` will match only `<a>`.
- `{m}` Specifies that exactly *m* copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six 'a' characters, but not five.
- `{m, n}` Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3, 5}` will match from 3 to 5 'a' characters. Omitting *m* specifies a lower bound of zero, and omitting *n* specifies an infinite upper bound. As an example, `a{4, }b` will match `aaaab` or a thousand 'a' characters followed by a `b`, but not `aaab`. The comma may not be omitted or the modifier would be confused with the previously described form.
- `{m, n}?` Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as few repetitions as possible. This is the non-greedy version of the previous qualifier. For example, on the 6-character string `'aaaaaa'`, `a{3, 5}` will match 5 'a' characters, while `a{3, 5}?` will only match 3 characters.
- '\' Either escapes special characters (permitting you to match characters like `'*'`, `'?'`, and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[] Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match 'a', 'm', or 'k'.
- Ranges of characters can be indicated by giving two characters and separating them by a `-`, for example `[a-z]` will match any lowercase ASCII letter, `[0-5][0-9]` will match all the two-digits numbers from 00 to 59, and `[0-9A-Fa-f]` will match any hexadecimal digit. If `-` is escaped (e.g. `[a\-z]`) or if it's placed as the first or last character (e.g. `[a-]`), it will match a literal `'-'`.

- Special characters lose their special meaning inside sets. For example, `[(+*)]` will match any of the literal characters `' (' , ' + ' , ' * ' , or ') '`.
- Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depends on whether [LOCALE](#) or [UNICODE](#) mode is in force.
- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is `' ^ '`, all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except `' 5 '`, and `[^^]` will match any character except `' ^ '`. `^` has no special meaning if it's not the first character in the set.
- To match a literal `'] '` inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[() [\] { }]` and `[] () [{ }]` will both match a parenthesis.

`' | ' A | B`, where A and B can be arbitrary REs, creates a regular expression that will match either A or B. An arbitrary number of REs can be separated by the `' | '` in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by `' | '` are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once A matches, B will not be tested further, even if it would produce a longer overall match. In other words, the `' | '` operator is never greedy. To match a literal `' | '`, use `\|`, or enclose it inside a character class, as in `[|]`.

(. . .) Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string with the `\number` special sequence, described below. To match the literals `' (' or ') '`, use `\ (or \)`, or enclose them inside a character class: `[() []]`.

(? . . .) This is an extension notation (a `' ? '` following a `' ('` is not meaningful otherwise). The first character after the `' ? '` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; `(? P <name> . . .)` is the only exception to this rule. Following are the currently supported extensions.

(? i L m s u x) (One or more letters from the set `' i ' , ' L ' , ' m ' , ' s ' , ' u ' , ' x ' .`) The group matches the empty string; the letters set the corresponding flags: [re.I](#) (ignore case), [re.L](#) (locale dependent), [re.M](#) (multi-line), [re.S](#) (dot matches all), [re.U](#) (Unicode dependent), and [re.X](#) (verbose), for the entire regular expression. (The flags are described in [Module Contents](#).) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the [re.compile\(\)](#) function.

Note that the `(? x)` flag changes how the expression is parsed. It should be used first in the expression string, or after one or more whitespace characters. If there are non-whitespace characters before the flag, the results are undefined.

(? : . . .) A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

(? P <name> . . .) Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is `(? P <quote> [' "]) . * ? (? P = quote)` (i.e. matching a string quoted with either single or double quotes):

| Context of reference to group “quote” | Ways to reference it |
|---|---|
| in the same pattern itself | <ul style="list-style-type: none"> • <code>(?P=quote)</code> (as shown) • <code>\1</code> |
| when processing match object <code>m</code> | <ul style="list-style-type: none"> • <code>m.group('quote')</code> • <code>m.end('quote')</code> (etc.) |
| in a string passed to the <code>repl</code> argument of <code>re.sub()</code> | <ul style="list-style-type: none"> • <code>\g<quote></code> • <code>\g<1></code> • <code>\1</code> |

`(?P=name)` A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

`(?#...)` A comment; the contents of the parentheses are simply ignored.

`(?=...)` Matches if `...` matches next, but doesn’t consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match `'Isaac '` only if it’s followed by `'Asimov'`.

`(?!...)` Matches if `...` doesn’t match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match `'Isaac '` only if it’s *not* followed by `'Asimov'`.

`(?<=...)` Matches if the current position in the string is preceded by a match for `...` that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in `abcdef`, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Group references are not supported even if they match strings of some fixed length. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the `search()` function rather than the `match()` function:

```
>>> import re
>>> m = re.search('(?<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search('(?!<=)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

`(?<!...)` Matches if the current position in the string is not preceded by a match for `...`. This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length and shouldn’t contain group references. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

`(?(id/name)yes-pattern|no-pattern)` Will try to match with `yes-pattern` if the group with given *id* or *name* exists, and with `no-pattern` if it doesn’t. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@\w+(?:\.\w+)+)(?(1)>)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'`.

New in version 2.4.

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not on the list, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

\number Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+) \1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'[' and ']'` of a character class, all numeric escapes are treated as characters.

\A Matches only at the start of the string.

\b Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of alphanumeric or underscore characters, so the end of a word is indicated by whitespace or a non-alphanumeric, non-underscore character. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning/end of the string, so the precise set of characters deemed to be alphanumeric depends on the values of the `UNICODE` and `LOCALE` flags. For example, `r'\bfoo\b'` matches `'foo'`, `'foo.'`, `'(foo)'`, `'bar foo baz'` but not `'foobar'` or `'foo3'`. Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

\B Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'py\B'` matches `'python'`, `'py3'`, `'py2'`, but not `'py'`, `'py.'`, or `'py!'`. `\B` is just the opposite of `\b`, so is also subject to the settings of `LOCALE` and `UNICODE`.

\d When the `UNICODE` flag is not specified, matches any decimal digit; this is equivalent to the set `[0-9]`. With `UNICODE`, it will match whatever is classified as a decimal digit in the Unicode character properties database.

\D When the `UNICODE` flag is not specified, matches any non-digit character; this is equivalent to the set `[^0-9]`. With `UNICODE`, it will match anything other than character marked as digits in the Unicode character properties database.

\s When the `UNICODE` flag is not specified, it matches any whitespace character, this is equivalent to the set `[\t\n\r\f\v]`. The `LOCALE` flag has no extra effect on matching of the space. If `UNICODE` is set, this will match the characters `[\t\n\r\f\v]` plus whatever is classified as space in the Unicode character properties database.

\S When the `UNICODE` flag is not specified, matches any non-whitespace character; this is equivalent to the set `[^\t\n\r\f\v]`. The `LOCALE` flag has no extra effect on non-whitespace match. If `UNICODE` is set, then any character not marked as space in the Unicode character properties database is matched.

\w When the `LOCALE` and `UNICODE` flags are not specified, matches any alphanumeric character and the underscore; this is equivalent to the set `[a-zA-Z0-9_]`. With `LOCALE`, it will match the set `[0-9_]` plus whatever characters are defined as alphanumeric for the current locale. If `UNICODE` is set, this will match the characters `[0-9_]` plus whatever is classified as alphanumeric in the Unicode character properties database.

\W When the `LOCALE` and `UNICODE` flags are not specified, matches any non-alphanumeric character; this is equivalent to the set `[^a-zA-Z0-9_]`. With `LOCALE`, it will match any character not in the set `[0-9_]`, and not defined as alphanumeric for the current locale. If `UNICODE` is set, this will match anything other than `[0-9_]` plus characters classified as not alphanumeric in the Unicode character properties database.

\Z Matches only at the end of the string.

If both `LOCALE` and `UNICODE` flags are included for a particular sequence, then `LOCALE` flag takes effect first followed by the `UNICODE`.

Most of the standard escapes supported by Python string literals are also accepted by the regular expression parser:

| | | | |
|-----------------|-----------------|-----------------|-----------------|
| <code>\a</code> | <code>\b</code> | <code>\f</code> | <code>\n</code> |
| <code>\r</code> | <code>\t</code> | <code>\v</code> | <code>\x</code> |
| <code>\\</code> | | | |

(Note that `\b` is used to represent word boundaries, and means “backspace” only inside character classes.)

Octal escapes are included in a limited form: If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in

length.

Mastering Regular Expressions Book on regular expressions by Jeffrey Friedl, published by O'Reilly. The second edition of the book no longer covers Python at all, but the first edition covered writing good regular expression patterns in great detail.

7.2.2 Module Contents

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

`re.compile(pattern, flags=0)`

Compile a regular expression pattern into a regular expression object, which can be used for matching using its `match()` and `search()` methods, described below.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the following variables, combined using bitwise OR (the `|` operator).

The sequence

```
prog = re.compile(pattern)
result = prog.match(string)
```

is equivalent to

```
result = re.match(pattern, string)
```

but using `re.compile()` and saving the resulting regular expression object for reuse is more efficient when the expression will be used several times in a single program.

Note: The compiled versions of the most recent patterns passed to `re.match()`, `re.search()` or `re.compile()` are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

`re.DEBUG`

Display debug information about compiled expression.

`re.I`

`re.IGNORECASE`

Perform case-insensitive matching; expressions like `[A-Z]` will match lowercase letters, too. This is not affected by the current locale. To get this effect on non-ASCII Unicode characters such as `ü` and `Û`, add the `UNICODE` flag.

`re.L`

`re.LOCALE`

Make `\w`, `\W`, `\b`, `\B`, `\s` and `\S` dependent on the current locale.

`re.M`

`re.MULTILINE`

When specified, the pattern character `'^'` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `'$'` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `'^'` matches only at the beginning of the string, and `'$'` only at the end of the string and immediately before the newline (if any) at the end of the string.

`re.S`

re.DOTALL

Make the `'.'` special character match any character at all, including a newline; without this flag, `'.'` will match anything *except* a newline.

re.U**re.UNICODE**

Make the `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` sequences dependent on the Unicode character properties database. Also enables non-ASCII matching for *IGNORECASE*.

New in version 2.0.

re.X**re.VERBOSE**

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d + # the integral part
                \.    # the decimal point
                \d *  # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

re.search (*pattern*, *string*, *flags=0*)

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding *MatchObject* instance. Return *None* if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

re.match (*pattern*, *string*, *flags=0*)

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding *MatchObject* instance. Return *None* if the string does not match the pattern; note that this is different from a zero-length match.

Note that even in *MULTILINE* mode, *re.match()* will only match at the beginning of the string and not at the beginning of each line.

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search()* vs. *match()*).

re.split (*pattern*, *string*, *maxsplit=0*, *flags=0*)

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list. (Incompatibility note: in the original Python 1.5 release, *maxsplit* was ignored. This has been fixed in later releases.)

```
>>> re.split('\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split('(\W+)', 'Words, words, words.')
['Words', '', ' ', 'words', '', ' ', 'words', '.', '']
>>> re.split('\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

If there are capturing groups in the separator and it matches at the start of the string, the result will start with an empty string. The same holds for the end of the string:

```
>>> re.split('(\W+)', '...words, words...')
['', '...', 'words', ',', ' ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list (e.g., if there's one capturing group in the separator, the 0th, the 2nd and so forth).

Note that *split* will never split a string on an empty pattern match. For example:

```
>>> re.split('x*', 'foo')
['foo']
>>> re.split("(?m)^\$", "foo\n\nbar\n")
['foo\n\nbar\n']
```

Changed in version 2.7: Added the optional flags argument.

re.findall (*pattern*, *string*, *flags*=0)

Return all non-overlapping matches of *pattern* in *string*, as a list of strings. The *string* is scanned left-to-right, and matches are returned in the order found. If one or more groups are present in the pattern, return a list of groups; this will be a list of tuples if the pattern has more than one group. Empty matches are included in the result.

Note: Due to the limitation of the current implementation the character following an empty match is not included in a next match, so `findall(r'^|\w+', 'two words')` returns `['', 'wo', 'words']` (note missed “t”). This is changed in Python 3.7.

New in version 1.5.2.

Changed in version 2.4: Added the optional flags argument.

re.finditer (*pattern*, *string*, *flags*=0)

Return an *iterator* yielding *MatchObject* instances over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result. See also the note about *findall()*.

New in version 2.2.

Changed in version 2.4: Added the optional flags argument.

re.sub (*pattern*, *repl*, *string*, *count*=0, *flags*=0)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes such as `\j` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*(\s*):',
...       r'static PyObject*\np_\1(void)\n{',
...       'def myfunc():')
'static PyObject*\np_myfunc(void)\n{'
```

If *repl* is a function, it is called for every non-overlapping occurrence of *pattern*. The function takes a single match object argument, and returns the replacement string. For example:

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
>>> re.sub('-{1,2}', dashrepl, 'pro---gram-files')
'pro--gram files'
```

(continues on next page)

(continued from previous page)

```
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

The pattern may be a string or an RE object.

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced. Empty matches for the pattern are replaced only when not adjacent to a previous match, so `sub('x*', '-', 'abc')` returns `'-a-b-c-'`.

In string-type *repl* arguments, in addition to the character escapes and backreferences described above, `\g<name>` will use the substring matched by the group named `name`, as defined by the `(?P<name>...)` syntax. `\g<number>` uses the corresponding group number; `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement such as `\g<2>0`. `\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character '0'. The backreference `\g<0>` substitutes in the entire substring matched by the RE.

Changed in version 2.7: Added the optional flags argument.

```
re.subn(pattern, repl, string, count=0, flags=0)
```

Perform the same operation as `sub()`, but return a tuple (`new_string`, `number_of_subs_made`).

Changed in version 2.7: Added the optional flags argument.

```
re.escape(pattern)
```

Escape all the characters in *pattern* except ASCII letters and numbers. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print re.escape('python.exe')
python\.exe

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print '['+re.escape(legal_chars)
[abcdefghijklmnopqrstuvwxyz0123456789\!#$%&'*\+|-.\^_\`|\~:]+

>>> operators = ['+', '-', '*', '/', '**']
>>> print '|'.join(map(re.escape, sorted(operators, reverse=True)))
\+|-|\+|\*\*|\*
```

```
re.purge()
```

Clear the regular expression cache.

```
exception re.error
```

Exception raised when a string passed to one of the functions here is not a valid regular expression (for example, it might contain unmatched parentheses) or when some other error occurs during compilation or matching. It is never an error if a string contains no match for a pattern.

7.2.3 Regular Expression Objects

```
class re.RegexObject
```

The *RegexObject* class supports the following methods and attributes:

search (*string*_{[, pos}_{[, endpos}]_])

Scan through *string* looking for a location where this regular expression produces a match, and return a corresponding *MatchObject* instance. Return *None* if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to 0. This is not completely equivalent to slicing the string; the `'^'` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is *endpos* characters long, so only the characters from *pos* to *endpos* - 1 will be searched for a match. If *endpos* is less than *pos*, no match will be found, otherwise, if *rx* is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")      # Match at index 0
<_sre.SRE_Match object at ...>
>>> pattern.search("dog", 1)   # No match; search doesn't include the "d"
```

match (*string*[, *pos*[, *endpos*]])

If zero or more characters at the *beginning* of *string* match this regular expression, return a corresponding *MatchObject* instance. Return *None* if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")       # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)    # Match as "o" is the 2nd character of "dog".
<_sre.SRE_Match object at ...>
```

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search()* vs. *match()*).

split (*string*, *maxsplit*=0)

Identical to the *split()* function, using the compiled pattern.

findall (*string*[, *pos*[, *endpos*]])

Similar to the *findall()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *match()*.

finditer (*string*[, *pos*[, *endpos*]])

Similar to the *finditer()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *match()*.

sub (*repl*, *string*, *count*=0)

Identical to the *sub()* function, using the compiled pattern.

subn (*repl*, *string*, *count*=0)

Identical to the *subn()* function, using the compiled pattern.

flags

The regex matching flags. This is a combination of the flags given to *compile()* and any *(?...)* inline flags in the pattern.

groups

The number of capturing groups in the pattern.

groupindex

A dictionary mapping any symbolic group names defined by *(?P<id>)* to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

pattern

The pattern string from which the RE object was compiled.

7.2.4 Match Objects

`class re.MatchObject`

Match objects always have a boolean value of `True`. Since `match()` and `search()` return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

Match objects support the following methods and attributes:

`expand(template)`

Return the string obtained by doing backslash substitution on the template string *template*, as done by the `sub()` method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group.

`group([group1, ...])`

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, *group1* defaults to zero (the whole match is returned). If a *groupN* argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range `[1..99]`, it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an `IndexError` exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)          # The entire match
'Isaac Newton'
>>> m.group(1)          # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)          # The second parenthesized subgroup.
'Newton'
>>> m.group(1, 2)       # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the *groupN* arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an `IndexError` exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(..)+", "a1b2c3") # Matches 3 times.
>>> m.group(1)                        # Returns only the last match.
'c3'
```

groups ([*default*])

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to *None*. (Incompatibility note: in the original Python 1.5 release, if the tuple was one element long, a string would be returned instead. In later versions (from 1.5.1 on), a singleton tuple is returned in such cases.)

For example:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to *None* unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(\d+)?", "24")
>>> m.groups() # Second group defaults to None.
('24', None)
>>> m.groups('0') # Now, the second group defaults to '0'.
('24', '0')
```

groupdict ([*default*])

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it defaults to *None*. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

start ([*group*])

end ([*group*])

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return *-1* if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to *m.group(g)*) is

```
m.string[m.start(g):m.end(g)]
```

Note that *m.start(group)* will equal *m.end(group)* if *group* matched a null string. For example, after *m = re.search('b(c?)', 'cba')*, *m.start(0)* is 1, *m.end(0)* is 2, *m.start(1)* and *m.end(1)* are both 2, and *m.start(2)* raises an *IndexError* exception.

An example that will remove *remove_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

span ([*group*])

For *MatchObject* *m*, return the 2-tuple (*m.start(group)*, *m.end(group)*). Note that if *group*

did not contribute to the match, this is `(-1, -1)`. `group` defaults to zero, the entire match.

pos

The value of `pos` which was passed to the `search()` or `match()` method of the `RegexObject`. This is the index into the string at which the RE engine started looking for a match.

endpos

The value of `endpos` which was passed to the `search()` or `match()` method of the `RegexObject`. This is the index into the string beyond which the RE engine will not go.

lastindex

The integer index of the last matched capturing group, or `None` if no group was matched at all. For example, the expressions `(a)b`, `((a)(b))`, and `((ab))` will have `lastindex == 1` if applied to the string `'ab'`, while the expression `(a)(b)` will have `lastindex == 2`, if applied to the same string.

lastgroup

The name of the last matched capturing group, or `None` if the group didn't have a name, or if no group was matched at all.

re

The regular expression object whose `match()` or `search()` method produced this `MatchObject` instance.

string

The string passed to `match()` or `search()`.

7.2.5 Examples

Checking For a Pair

In this example, we'll use the following helper function to display match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, "a" for ace, "k" for king, "q" for queen, "j" for jack, "t" for 10, and "2" through "9" representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q"))    # Valid.
'<Match: 'akt5q', groups=()>'
>>> displaymatch(valid.match("akt5e"))    # Invalid.
'<Match: 'akt5e', groups=()>'
>>> displaymatch(valid.match("akt"))      # Invalid.
'<Match: 'akt', groups=()>'
>>> displaymatch(valid.match("727ak"))    # Valid.
'<Match: '727ak', groups=()>'
```

That last hand, "727ak", contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r".*(.)\1")
>>> displaymatch(pair.match("717ak"))      # Pair of 7s.
'<Match: '717', groups=('7',)>'
```

(continues on next page)

(continued from previous page)

```
>>> displaymatch(pair.match("718ak"))      # No pairs.
>>> displaymatch(pair.match("354aa"))      # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the `group()` method of `MatchObject` in the following manner:

```
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pysHELL#23>", line 1, in <module>
    re.match(r".*(.)*\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

Simulating `scanf()`

Python does not currently have an equivalent to `scanf()`. Regular expressions are generally more powerful, though also more verbose, than `scanf()` format strings. The table below offers some more-or-less equivalent mappings between `scanf()` format tokens and regular expressions.

| <code>scanf()</code> Token | Regular Expression |
|-----------------------------|--|
| <code>%c</code> | <code>.</code> |
| <code>%5c</code> | <code>.{5}</code> |
| <code>%d</code> | <code>[+-]?\d+</code> |
| <code>%e, %E, %f, %g</code> | <code>[+-]?(\d+(\.\d*)? \.\d+)([eE][+-]?\d+)?</code> |
| <code>%i</code> | <code>[+-]?(0[xX] \dA-Za-z-f)+ 0[0-7]* \d+</code> |
| <code>%o</code> | <code>[+-]?[0-7]+</code> |
| <code>%s</code> | <code>\S+</code> |
| <code>%u</code> | <code>\d+</code> |
| <code>%x, %X</code> | <code>[+-]?(0[xX])?[\dA-Za-z-f]+</code> |

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a `scanf()` format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

search() vs. match()

Python offers two different primitive operations based on regular expressions: `re.match()` checks for a match only at the beginning of the string, while `re.search()` checks for a match anywhere in the string (this is what Perl does by default).

For example:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("c", "abcdef")     # Match
<_sre.SRE_Match object at ...>
```

Regular expressions beginning with `'^'` can be used with `search()` to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("^c", "abcdef")    # No match
>>> re.search("^a", "abcdef")    # Match
<_sre.SRE_Match object at ...>
```

Note however that in *MULTILINE* mode `match()` only matches at the beginning of the string, whereas using `search()` with a regular expression beginning with `'^'` will match at the beginning of each line.

```
>>> re.match('X', 'A\nB\nX', re.MULTILINE) # No match
>>> re.search('X', 'A\nB\nX', re.MULTILINE) # Match
<_sre.SRE_Match object at ...>
```

Making a Phonebook

`split()` splits a string into a list delimited by the passed pattern. The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax:

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
 'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
 'Frank Burger: 925.541.7625 662 South Dogwood Way',
 'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of `split()` because the address has spaces, our splitting pattern, in it:

```
>>> [re.split("?:? ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `?:?` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of 4, we could separate the house number from the street name:

```
>>> [re.split("?:? ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

Text Munging

`sub()` replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using `sub()` with a function to “munge” text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlodbk, pslae reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reorpt yuor asnebces potlmpy.'
```

Finding all Adverbs

`findall()` matches *all* occurrences of a pattern, not just the first one as `search()` does. For example, if a writer wanted to find all of the adverbs in some text, they might use `findall()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly", text)
['carefully', 'quickly']
```

Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, `finditer()` is useful as it provides instances of `MatchObject` instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use `finditer()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly", text):
...     print '%02d-%02d: %s' % (m.start(), m.end(), m.group(0))
07-16: carefully
40-47: quickly
```

Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")
<_sre.SRE_Match object at ...>
>>> re.match("\\W(.)\\1\\W", " ff ")
<_sre.SRE_Match object at ...>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\"`. Without raw string notation, one must use `"\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\\", r"\\")
<_sre.SRE_Match object at ...>
>>> re.match("\\\\", r"\\")
<_sre.SRE_Match object at ...>
```

7.3 struct — Interpret strings as packed binary data

This module performs conversions between Python values and C structs represented as Python strings. This can be used in handling binary data stored in files or from network connections, among other sources. It uses *Format Strings* as compact descriptions of the layout of the C structs and the intended conversion to/from Python values.

Note: By default, the result of packing a given C struct includes pad bytes in order to maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. This behavior is chosen so that the bytes of a packed struct correspond exactly to the layout in memory of the corresponding C struct. To handle platform-independent data formats or omit implicit pad bytes, use `standard` size and alignment instead of `native` size and alignment: see *Byte Order, Size, and Alignment* for details.

7.3.1 Functions and Exceptions

The module defines the following exception and functions:

exception `struct.error`

Exception raised on various occasions; argument is a string describing what is wrong.

struct.pack (*fmt*, *v1*, *v2*, ...)

Return a string containing the values *v1*, *v2*, ... packed according to the given format. The arguments must match the values required by the format exactly.

struct.pack_into (*fmt*, *buffer*, *offset*, *v1*, *v2*, ...)

Pack the values *v1*, *v2*, ... according to the given format, write the packed bytes into the writable *buffer* starting at *offset*. Note that the offset is a required argument.

New in version 2.5.

struct.unpack (*fmt*, *string*)

Unpack the string (presumably packed by `pack(fmt, ...)`) according to the given format. The result is a tuple even if it contains exactly one item. The string must contain exactly the amount of data required by the format (`len(string)` must equal `calcsiz(fmt)`).

```
struct.unpack_from(fmt, buffer[, offset=0])
```

Unpack the *buffer* according to the given format. The result is a tuple even if it contains exactly one item. The *buffer* must contain at least the amount of data required by the format (`len(buffer[offset:])` must be at least `calcsize(fmt)`).

New in version 2.5.

```
struct.calcsize(fmt)
```

Return the size of the struct (and hence of the string) corresponding to the given format.

7.3.2 Format Strings

Format strings are the mechanism used to specify the expected layout when packing and unpacking data. They are built up from *Format Characters*, which specify the type of data being packed/unpacked. In addition, there are special characters for controlling the *Byte Order, Size, and Alignment*.

Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler).

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table:

| Character | Byte order | Size | Alignment |
|-----------|------------------------|----------|-----------|
| @ | native | native | native |
| = | native | standard | none |
| < | little-endian | standard | none |
| > | big-endian | standard | none |
| ! | network (= big-endian) | standard | none |

If the first character is not one of these, '@' is assumed.

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86 and AMD64 (x86-64) are little-endian; Motorola 68000 and PowerPC G5 are big-endian; ARM and Intel Itanium feature switchable endianness (bi-endian). Use `sys.byteorder` to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the *Format Characters* section.

Note the difference between '@' and '=': both use native byte order, but the size and alignment of the latter is standardized.

The form '!' is available for those poor souls who claim they can't remember whether network byte order is big-endian or little-endian.

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of '<' or '>'.

Notes:

- (1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.
- (2) No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.

- (3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See [Examples](#).

Format Characters

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The ‘Standard size’ column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of '<', '>', '!' or '='. When using native size, the size of the packed value is platform-dependent.

| Format | C Type | Python type | Standard size | Notes |
|--------|--------------------|--------------------|---------------|----------|
| x | pad byte | no value | | |
| c | char | string of length 1 | 1 | |
| b | signed char | integer | 1 | (3) |
| B | unsigned char | integer | 1 | (3) |
| ? | _Bool | bool | 1 | (1) |
| h | short | integer | 2 | (3) |
| H | unsigned short | integer | 2 | (3) |
| i | int | integer | 4 | (3) |
| I | unsigned int | integer | 4 | (3) |
| l | long | integer | 4 | (3) |
| L | unsigned long | integer | 4 | (3) |
| q | long long | integer | 8 | (2), (3) |
| Q | unsigned long long | integer | 8 | (2), (3) |
| f | float | float | 4 | (4) |
| d | double | float | 8 | (4) |
| s | char[] | string | | |
| p | char[] | string | | |
| P | void * | integer | | (5), (3) |

Notes:

- (1) The '?' conversion code corresponds to the `_Bool` type defined by C99. If this type is not available, it is simulated using a `char`. In standard mode, it is always represented by one byte.

New in version 2.6.

- (2) The 'q' and 'Q' conversion codes are available in native mode only if the platform C compiler supports C long long, or, on Windows, `__int64`. They are always available in standard modes.

New in version 2.2.

- (3) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing. If no `__index__()` method exists, or the call to `__index__()` raises `TypeError`, then the `__int__()` method is tried. However, the use of `__int__()` is deprecated, and will raise `DeprecationWarning`.

Changed in version 2.7: Use of the `__index__()` method for non-integers is new in 2.7.

Changed in version 2.7: Prior to version 2.7, not all integer conversion codes would use the `__int__()` method to convert, and `DeprecationWarning` was raised only for float arguments.

- (4) For the 'f' and 'd' conversion codes, the packed representation uses the IEEE 754 binary32 (for 'f') or binary64 (for 'd') format, regardless of the floating-point format used by the platform.

- (5) The 'P' format character is only available for the native byte ordering (selected as the default or with the '@' byte order character). The byte order character '=' chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the 'P' format is not available.

A format character may be preceded by an integral repeat count. For example, the format string '4h' means exactly the same as 'hhhh'.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

For the 's' format character, the count is interpreted as the size of the string, not a repeat count like for the other format characters; for example, '10s' means a single 10-byte string, while '10c' means 10 characters. If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting string always has exactly the specified number of bytes. As a special case, '0s' means a single, empty string (while '0c' means 0 characters).

The 'p' format character encodes a “Pascal string”, meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to `pack()` is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it is padded with null bytes so that exactly `count` bytes in all are used. Note that for `unpack()`, the 'p' format character consumes `count` bytes, but that the string returned can never contain more than 255 characters.

For the 'P' format character, the return value is a Python integer or long integer, depending on the size needed to hold a pointer when it has been cast to an integer type. A `NULL` pointer will always be returned as the Python integer 0. When packing pointer-sized values, Python integer or long integer objects may be used. For example, the Alpha and Merced processors use 64-bit pointer values, meaning a Python long integer will be used to hold the pointer; other platforms use 32-bit pointers and will use a Python integer.

For the '?' format character, the return value is either `True` or `False`. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be `True` when unpacking.

Examples

Note: All examples assume a native byte order, size, and alignment with a big-endian machine.

A basic example of packing/unpacking three integers:

```
>>> from struct import *
>>> pack('hhl', 1, 2, 3)
'\x00\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('hhl', '\x00\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('hhl')
8
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = 'raymond \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name='raymond ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size since the padding needed to satisfy alignment requirements is different:

```
>>> pack('ci', '*', 0x12131415)
'*\x00\x00\x00\x12\x13\x14\x15'
>>> pack('ic', 0x12131415, '*')
'\x12\x13\x14\x15*'
>>> calcsizes('ci')
8
>>> calcsizes('ic')
5
```

The following format 'llh01' specifies two pad bytes at the end, assuming longs are aligned on 4-byte boundaries:

```
>>> pack('llh01', 1, 2, 3)
'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

This only works when native size and alignment are in effect; standard size and alignment does not enforce any alignment.

Module `array` Packed binary storage of homogeneous data.

Module `xdrlib` Packing and unpacking of XDR data.

7.3.3 Classes

The `struct` module also defines the following type:

class `struct.Struct` (*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling the `struct` functions with the same format since the format string only needs to be compiled once.

New in version 2.5.

Compiled Struct objects support the following methods and attributes:

pack (*v1*, *v2*, ...)

Identical to the `pack()` function, using the compiled format. (`len(result)` will equal `self.size`.)

pack_into (*buffer*, *offset*, *v1*, *v2*, ...)

Identical to the `pack_into()` function, using the compiled format.

unpack (*string*)

Identical to the `unpack()` function, using the compiled format. (`len(string)` must equal `self.size`).

unpack_from (*buffer*, *offset*=0)

Identical to the `unpack_from()` function, using the compiled format. (`len(buffer[offset:])` must be at least `self.size`).

format

The format string used to construct this Struct object.

size

The calculated size of the struct (and hence of the string) corresponding to *format*.

7.4 difflib — Helpers for computing deltas

New in version 2.1.

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce difference information in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the *filecmp* module.

class difflib.SequenceMatcher

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name “gestalt pattern matching.” The idea is to find the longest contiguous matching subsequence that contains no “junk” elements (the Ratcliff and Obershelp algorithm doesn't address junk). The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that “look right” to people.

Timing: The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. *SequenceMatcher* is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

Automatic junk heuristic: *SequenceMatcher* supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as “popular” and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the *autojunk* argument to *False* when creating the *SequenceMatcher*.

New in version 2.7.1: The *autojunk* parameter.

class difflib.Differ

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses *SequenceMatcher* both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a *Differ* delta begins with a two-letter code:

| Code | Meaning |
|-------|---|
| '- ' | line unique to sequence 1 |
| '+' ' | line unique to sequence 2 |
| ' ' ' | line common to both sequences |
| '?' ' | line not present in either input sequence |

Lines beginning with ‘?’ attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain tab characters.

class difflib.HtmlDiff

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

__init__ (*tabsize=8, wrapcolumn=None, linejunk=None, charjunk=IS_CHARACTER_JUNK*)
 Initializes instance of *HtmlDiff*.

tabsize is an optional keyword argument to specify tab stop spacing and defaults to 8.

wrapcolumn is an optional keyword to specify column number where lines are broken and wrapped, defaults to *None* where lines are not wrapped.

linejunk and *charjunk* are optional keyword arguments passed into *ndiff()* (used by *HtmlDiff* to generate the side by side HTML differences). See *ndiff()* documentation for argument default values and descriptions.

The following methods are public:

make_file (*fromlines*, *tolines* [, *fromdesc*][, *todesc*][, *context*][, *numlines*])

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

fromdesc and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

context and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to 5. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using the “next” hyperlinks (setting to zero would cause the “next” hyperlinks to place the next difference highlight at the top of the browser without any leading context).

make_table (*fromlines*, *tolines* [, *fromdesc*][, *todesc*][, *context*][, *numlines*])

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the *make_file()* method.

`Tools/scripts/diff.py` is a command-line front-end to this class and contains a good example of its use.

New in version 2.4.

`difflib.context_diff(a, b[, fromfile][, tofile][, fromfiledate][, tofiledate][, n][, lineterm])`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from *file.readlines()* result in diffs that are suitable for use with *file.writelines()* since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> for line in context_diff(s1, s2, fromfile='before.py', tofile='after.py'):
...     sys.stdout.write(line) # doctest: +NORMALIZE_WHITESPACE
*** before.py
--- after.py
*****
*** 1,4 ***
! bacon
! eggs
! ham
  guido
--- 1,4 ----
! python
```

(continues on next page)

(continued from previous page)

```
! eggy
! hamster
  guido
```

See [A command-line interface to `diff`](#) for a more detailed example.

New in version 2.3.

`diff`.`get_close_matches`(*word*, *possibilities*[, *n*][, *cutoff*])

Return a list of the best “good enough” matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don’t score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('apple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

`diff`.`ndiff`(*a*, *b*[, *linejunk*][, *charjunk*])

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`):

linejunk: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is (`None`), starting with Python 2.3. Before then, the default was the module-level function `IS_LINE_JUNK()`, which filters out lines without visible characters, except for at most one pound character (`'#'`). As of Python 2.3, the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than the pre-2.3 default.

charjunk: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; note: bad idea to include newline in this!).

`Tools/scripts/ndiff.py` is a command-line front-end to this function.

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(1),
...             'ore\ntree\nemu\n'.splitlines(1))
>>> print ''.join(diff),
- one
? ^
+ ore
? ^
- two
- three
? -
+ tree
+ emu
```

`difflib.restore(sequence, which)`

Return one of the two sequences that generated a delta.

Given a *sequence* produced by `Differ.compare()` or `ndiff()`, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

Example:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(1),
...              'ore\ntree\nemu\n'.splitlines(1))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print ''.join(restore(diff, 1)),
one
two
three
>>> print ''.join(restore(diff, 2)),
ore
tree
emu
```

`difflib.unified_diff(a, b[, fromfile][, tofile][, fromfiledate][, tofiledate][, n][, lineterm])`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `---`, `+++`, or `@@`) are created with a trailing newline. This is helpful so that inputs created from `file.readlines()` result in diffs that are suitable for use with `file.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> for line in unified_diff(s1, s2, fromfile='before.py', tofile='after.py'):
...     sys.stdout.write(line) # doctest: +NORMALIZE_WHITESPACE
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
 guido
```

See [A command-line interface to *difflib*](#) for a more detailed example.

New in version 2.3.

`difflib.IS_LINE_JUNK(line)`

Return true for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single `'#'`, otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` before Python 2.3.

`difflib.IS_CHARACTER_JUNK(ch)`

Return true for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

Pattern Matching: The Gestalt Approach Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in *Dr. Dobbs' Journal* in July, 1988.

7.4.1 SequenceMatcher Objects

The `SequenceMatcher` class has this constructor:

class `difflib.SequenceMatcher` (*isjunk=None*, *a=""*, *b=""*, *autojunk=True*)

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is “junk” and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: 0`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you’re comparing lines as sequences of characters, and don’t want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

New in version 2.7.1: The *autojunk* parameter.

`SequenceMatcher` objects have the following methods:

set_seqs (*a*, *b*)

Set the two sequences to be compared.

`SequenceMatcher` computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

set_seq1 (*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

set_seq2 (*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

find_longest_match (*alo*, *ahi*, *blo*, *bhi*)

Find longest matching block in `a[alo:ahi]` and `b[blo:bhi]`.

If *isjunk* was omitted or `None`, `find_longest_match()` returns (*i*, *j*, *k*) such that `a[i:i+k]` is equal to `b[j:j+k]`, where `alo <= i <= i+k <= ahi` and `blo <= j <= j+k <= bhi`. For all (*i'*, *j'*, *k'*) meeting those conditions, the additional conditions `k >= k'`, `i <= i'`, and if `i == i'`, `j <= j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, "abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching

(only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents ' abcd' from matching the ' abcd' at the tail end of the second sequence directly. Instead only the 'abcd' can match, and matches the leftmost 'abcd' in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns (a_{lo}, b_{lo}, 0).

Changed in version 2.6: This method returns a *named tuple* Match(a, b, size).

get_matching_blocks()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form (i, j, n), and means that a[i:i+n] == b[j:j+n]. The triples are monotonically increasing in i and j.

The last triple is a dummy, and has the value (len(a), len(b), 0). It is the only triple with n == 0. If (i, j, n) and (i', j', n') are adjacent triples in the list, and the second is not the last triple in the list, then i+n < i' or j+n < j'; in other words, adjacent triples always describe non-adjacent equal blocks.

Changed in version 2.5: The guarantee that adjacent triples always describe non-adjacent blocks was implemented.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

get_opcodes()

Return list of 5-tuples describing how to turn a into b. Each tuple is of the form (tag, i1, i2, j1, j2). The first tuple has i1 == j1 == 0, and remaining tuples have i1 equal to the i2 from the preceding tuple, and, likewise, j1 equal to the previous j2.

The tag values are strings, with these meanings:

| Value | Meaning |
|-----------|---|
| 'replace' | a[i1:i2] should be replaced by b[j1:j2]. |
| 'delete' | a[i1:i2] should be deleted. Note that j1 == j2 in this case. |
| 'insert' | b[j1:j2] should be inserted at a[i1:i1]. Note that i1 == i2 in this case. |
| 'equal' | a[i1:i2] == b[j1:j2] (the sub-sequences are equal). |

For example:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print ("%7s a[%d:%d] (%s) b[%d:%d] (%s)" %
...             (tag, i1, i2, a[i1:i2], j1, j2, b[j1:j2]))
delete a[0:1] (q) b[0:0] ()
equal a[1:3] (ab) b[0:2] (ab)
replace a[3:4] (x) b[2:3] (y)
equal a[4:6] (cd) b[3:5] (cd)
insert a[6:6] () b[5:6] (f)
```

get_grouped_opcodes (*n*)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by *get_opcodes*(), this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as *get_opcodes*().

New in version 2.3.

ratio ()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is $2.0 * M / T$. Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if *get_matching_blocks*() or *get_opcodes*() hasn't already been called, in which case you may want to try *quick_ratio*() or *real_quick_ratio*() first to get an upper bound.

quick_ratio ()

Return an upper bound on *ratio*() relatively quickly.

real_quick_ratio ()

Return an upper bound on *ratio*() very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although *quick_ratio*() and *real_quick_ratio*() are always at least as large as *ratio*():

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

7.4.2 SequenceMatcher Examples

This example compares two strings, considering blanks to be “junk:”

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                       "private Thread currentThread;",
...                       "private volatile Thread currentThread;")
```

ratio() returns a float in [0, 1], measuring the similarity of the sequences. As a rule of thumb, a *ratio*() value over 0.6 means the sequences are close matches:

```
>>> print round(s.ratio(), 3)
0.866
```

If you're only interested in where the sequences match, *get_matching_blocks*() is handy:

```
>>> for block in s.get_matching_blocks():
...     print "a[%d] and b[%d] match for %d elements" % block
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by `get_matching_blocks()` is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use `get_opcodes()`:

```
>>> for opcode in s.get_opcodes():
...     print "%6s a[%d:%d] b[%d:%d]" % opcode
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

- The `get_close_matches()` function in this module which shows how simple code building on `SequenceMatcher` can be used to do useful work.
- Simple version control recipe for a small application built with `SequenceMatcher`.

7.4.3 Differ Objects

Note that `Differ`-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The `Differ` class has this constructor:

```
class difflib.Differ([linejunk[, charjunk]])
```

Optional keyword parameters `linejunk` and `charjunk` are for filter functions (or `None`):

`linejunk`: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

`charjunk`: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

`Differ` objects are used (deltas generated) via a single method:

```
compare(a, b)
```

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the `readlines()` method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the `writelines()` method of a file-like object.

7.4.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the `readlines()` method of file-like objects):

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(1)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
```

(continues on next page)

(continued from previous page)

```
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3.   Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(1)
```

Next we instantiate a `Differ` object:

```
>>> d = Differ()
```

Note that when instantiating a `Differ` object we may pass functions to filter out line and character “junk.” See the `Differ()` constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let’s pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
[' 1. Beautiful is better than ugly.\n',
'- 2. Explicit is better than implicit.\n',
'- 3. Simple is better than complex.\n',
'+ 3.   Simple is better than complex.\n',
'?   ++\n',
'- 4. Complex is better than complicated.\n',
'?      ^               ---- ^\n',
'+ 4. Complicated is better than complex.\n',
'?      ++++ ^          ^\n',
'+ 5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3.   Simple is better than complex.
?   ++
- 4. Complex is better than complicated.
?      ^               ---- ^
+ 4. Complicated is better than complex.
?      ++++ ^          ^
+ 5. Flat is better than nested.
```

7.4.5 A command-line interface to `diff`lib

This example shows how to use `diff`lib to create a `diff`-like utility. It is also contained in the Python source distribution, as `Tools/scripts/diff.py`.

```
""" Command line interface to difflib.py providing diffs in four formats:
* ndiff:      lists every line and highlights interline changes.
```

(continues on next page)

(continued from previous page)

```

* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, time, difflib, optparse

def main():
    # Configure the option parser
    usage = "usage: %prog [options] fromfile tofile"
    parser = optparse.OptionParser(usage)
    parser.add_option("-c", action="store_true", default=False,
                      help='Produce a context format diff (default)')
    parser.add_option("-u", action="store_true", default=False,
                      help='Produce a unified format diff')
    hlp = 'Produce HTML side by side diff (can use -c and -l in conjunction)'
    parser.add_option("-m", action="store_true", default=False, help=hlp)
    parser.add_option("-n", action="store_true", default=False,
                      help='Produce a ndiff format diff')
    parser.add_option("-l", "--lines", type="int", default=3,
                      help='Set number of context lines (default 3)')
    (options, args) = parser.parse_args()

    if len(args) == 0:
        parser.print_help()
        sys.exit(1)
    if len(args) != 2:
        parser.error("need to specify both a fromfile and tofile")

    n = options.lines
    fromfile, tofile = args # as specified in the usage string

    # we're passing these as arguments to the diff function
    fromdate = time.ctime(os.stat(fromfile).st_mtime)
    todater = time.ctime(os.stat(tofile).st_mtime)
    with open(fromfile, 'U') as f:
        fromlines = f.readlines()
    with open(tofile, 'U') as f:
        tolines = f.readlines()

    if options.u:
        diff = difflib.unified_diff(fromlines, tolines, fromfile, tofile,
                                    fromdate, todater, n=n)
    elif options.n:
        diff = difflib.ndiff(fromlines, tolines)
    elif options.m:
        diff = difflib.HtmlDiff().make_file(fromlines, tolines, fromfile,
                                             tofile, context=options.c,
                                             numlines=n)
    else:
        diff = difflib.context_diff(fromlines, tolines, fromfile, tofile,
                                    fromdate, todater, n=n)

    # we're using writelines because diff is a generator
    sys.stdout.writelines(diff)

```

(continues on next page)

(continued from previous page)

```
if __name__ == '__main__':
    main()
```

7.5 StringIO — Read and write strings as files

This module implements a file-like class, *StringIO*, that reads and writes a string buffer (also known as *memory files*). See the description of file objects for operations (section *File Objects*). (For standard strings, see *str* and *unicode*.)

class StringIO.**StringIO**([*buffer*])

When a *StringIO* object is created, it can be initialized to an existing string by passing the string to the constructor. If no string is given, the *StringIO* will start empty. In both cases, the initial file position starts at zero.

The *StringIO* object can accept either Unicode or 8-bit strings, but mixing the two may take some care. If both are used, 8-bit strings that cannot be interpreted as 7-bit ASCII (that use the 8th bit) will cause a *UnicodeError* to be raised when *getvalue()* is called.

The following methods of *StringIO* objects require special mention:

StringIO.**getvalue**()

Retrieve the entire contents of the “file” at any time before the *StringIO* object’s *close()* method is called. See the note above for information about mixing Unicode and 8-bit strings; such mixing can cause this method to raise *UnicodeError*.

StringIO.**close**()

Free the memory buffer. Attempting to do further operations with a closed *StringIO* object will raise a *ValueError*.

Example usage:

```
import StringIO

output = StringIO.StringIO()
output.write('First line.\n')
print >>output, 'Second line.'

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

7.6 cStringIO — Faster version of StringIO

The module *cStringIO* provides an interface similar to that of the *StringIO* module. Heavy use of *StringIO*. *StringIO* objects can be made more efficient by using the function *StringIO()* from this module instead.

cStringIO.StringIO([*s*])

Return a StringIO-like stream for reading or writing.

Since this is a factory function which returns objects of built-in types, there’s no way to build your own version using subclassing. It’s not possible to set attributes on it. Use the original *StringIO* module in those cases.

Unlike the *StringIO* module, this module is not able to accept Unicode strings that cannot be encoded as plain ASCII strings.

Another difference from the *StringIO* module is that calling *StringIO()* with a string parameter creates a read-only object. Unlike an object created without a string parameter, it does not have write methods. These objects are not generally visible. They turn up in tracebacks as *StringI* and *StringO*.

The following data objects are provided as well:

cStringIO.InputType

The type object of the objects created by calling *StringIO()* with a string parameter.

cStringIO.OutputType

The type object of the objects returned by calling *StringIO()* with no parameters.

There is a C API to the module as well; refer to the module source for more information.

Example usage:

```
import cStringIO

output = cStringIO.StringIO()
output.write('First line.\n')
print >>output, 'Second line.'

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

7.7 textwrap — Text wrapping and filling

New in version 2.3.

Source code: [Lib/textwrap.py](#)

The *textwrap* module provides two convenience functions, *wrap()* and *fill()*, as well as *TextWrapper*, the class that does all the work, and a utility function *dedent()*. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of *TextWrapper* for efficiency.

textwrap.wrap(*text*[, *width*[, ...]])

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of *TextWrapper*, documented below. *width* defaults to 70.

See the *TextWrapper.wrap()* method for additional details on how *wrap()* behaves.

textwrap.fill(*text*[, *width*[, ...]])

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph. *fill()* is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

Both `wrap()` and `fill()` work by creating a `TextWrapper` instance and calling a single method on it. That instance is not reused, so for applications that wrap/fill many text strings, it will be more efficient for you to create your own `TextWrapper` object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless `TextWrapper.break_long_words` is set to false.

An additional utility function, `dedent()`, is provided to remove indentation from strings that have unwanted whitespace to the left of the text.

`textwrap.dedent(text)`

Remove any common leading whitespace from every line in `text`.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines `" hello"` and `"\thello"` are considered to have no common leading whitespace. (This behaviour is new in Python 2.5; older versions of this module incorrectly expanded tabs before searching for common leading whitespace.)

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

For example:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
hello
    world
'''
    print repr(s)          # prints '    hello\n        world\n    '
    print repr(dedent(s))  # prints 'hello\n    world\n'
```

class `textwrap.TextWrapper(...)`

The `TextWrapper` constructor accepts a number of optional keyword arguments. Each argument corresponds to one instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can re-use the same `TextWrapper` object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The `TextWrapper` instance attributes (and keyword arguments to the constructor) are as follows:

width

(default: 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than `width`, `TextWrapper` guarantees that no output line will be longer than `width` characters.

expand_tabs

(default: True) If true, then all tab characters in `text` will be expanded to spaces using the `expandtabs()` method of `text`.

replace_whitespace

(default: `True`) If true, after tab expansion but before wrapping, the `wrap()` method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

Note: If `expand_tabs` is false and `replace_whitespace` is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

Note: If `replace_whitespace` is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using `str.splitlines()` or similar) which are wrapped separately.

drop_whitespace

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

New in version 2.6: Whitespace was always dropped in earlier versions.

initial_indent

(default: `' '`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

subsequent_indent

(default: `' '`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

fix_sentence_endings

(default: `False`) If true, `TextWrapper` attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `'!'`, or `'?'`, possibly followed by one of `'\"'` or `'\"'`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between “Dr.” in

```
[...] Dr. Frankenstein's monster [...]
```

and “Spot.” in

```
[...] See Spot. See Spot run [...]
```

`fix_sentence_endings` is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of “lowercase letter,” and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

break_long_words

(default: `True`) If true, then words longer than `width` will be broken in order to ensure that no lines are longer than `width`. If it is false, long words will not be broken, and some lines may be longer than `width`. (Long words will be put on a line by themselves, in order to minimize the amount by which `width` is exceeded.)

break_on_hyphens

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places

for line breaks, but you need to set `break_long_words` to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

New in version 2.6.

`TextWrapper` also provides two public methods, analogous to the module-level convenience functions:

wrap (*text*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the `TextWrapper` instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

fill (*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

7.8 codecs — Codec registry and base classes

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry which manages the codec and error handling lookup process.

It defines the following functions:

`codecs.encode` (*obj* [, *encoding* [, *errors*]])

Encodes *obj* using the codec registered for *encoding*. The default encoding is 'ascii'.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeEncodeError`). Refer to [Codec Base Classes](#) for more information on codec error handling.

New in version 2.4.

`codecs.decode` (*obj* [, *encoding* [, *errors*]])

Decodes *obj* using the codec registered for *encoding*. The default encoding is 'ascii'.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeDecodeError`). Refer to [Codec Base Classes](#) for more information on codec error handling.

New in version 2.4.

`codecs.register` (*search_function*)

Register a codec search function. Search functions are expected to take one argument, the encoding name in all lower case letters, and return a `CodecInfo` object having the following attributes:

- `name` The name of the encoding;
- `encode` The stateless encoding function;
- `decode` The stateless decoding function;
- `incrementalencoder` An incremental encoder class or factory function;
- `incrementaldecoder` An incremental decoder class or factory function;
- `streamwriter` A stream writer class or factory function;
- `streamreader` A stream reader class or factory function.

The various functions or classes take the following arguments:

encode and *decode*: These must be functions or methods which have the same interface as the `encode()`/`decode()` methods of `Codec` instances (see [Codec Interface](#)). The functions/methods are expected to work in a stateless mode.

incrementalencoder and *incrementaldecoder*: These have to be factory functions providing the following interface:

```
factory(errors='strict')
```

The factory functions must return objects providing the interfaces defined by the base classes *IncrementalEncoder* and *IncrementalDecoder*, respectively. Incremental codecs can maintain state.

streamreader and *streamwriter*: These have to be factory functions providing the following interface:

```
factory(stream, errors='strict')
```

The factory functions must return objects providing the interfaces defined by the base classes *StreamReader* and *StreamWriter*, respectively. Stream codecs can maintain state.

Possible values for errors are

- 'strict': raise an exception in case of an encoding error
- 'replace': replace malformed data with a suitable replacement marker, such as '?' or '\ufffd'
- 'ignore': ignore malformed data and continue without further notice
- 'xmlcharrefreplace': replace with the appropriate XML character reference (for encoding only)
- 'backslashreplace': replace with backslashed escape sequences (for encoding only)

as well as any other error handling name defined via *register_error()*.

In case a search function cannot find a given encoding, it should return *None*.

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a *CodecInfo* object as defined above.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no *CodecInfo* object is found, a *LookupError* is raised. Otherwise, the *CodecInfo* object is stored in the cache and returned to the caller.

To simplify access to the various codecs, the module provides these additional functions which use *lookup()* for the codec lookup:

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental encoder.

New in version 2.5.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental decoder.

New in version 2.5.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its `StreamReader` class or factory function.

Raises a `LookupError` in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its `StreamWriter` class or factory function.

Raises a `LookupError` in case the encoding cannot be found.

`codecs.register_error(name, error_handler)`

Register the error handling function `error_handler` under the name `name`. `error_handler` will be called during encoding and decoding in case of an error, when `name` is specified as the errors parameter.

For encoding `error_handler` will be called with a `UnicodeEncodeError` instance, which contains information about the location of the error. The error handler must either raise this or a different exception or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The encoder will encode the replacement and continue encoding the original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an `IndexError` will be raised.

Decoding and translating works similar, except `UnicodeDecodeError` or `UnicodeTranslateError` will be passed to the handler and that the replacement from the error handler will be put into the output directly.

`codecs.lookup_error(name)`

Return the error handler previously registered under the name `name`.

Raises a `LookupError` in case the handler cannot be found.

`codecs.strict_errors(exception)`

Implements the `strict` error handling: each encoding or decoding error raises a `UnicodeError`.

`codecs.replace_errors(exception)`

Implements the `replace` error handling: malformed data is replaced with a suitable replacement character such as `'?'` in bytestrings and `'\ufffd'` in Unicode strings.

`codecs.ignore_errors(exception)`

Implements the `ignore` error handling: malformed data is ignored and encoding or decoding is continued without further notice.

`codecs.xmlcharrefreplace_errors(exception)`

Implements the `xmlcharrefreplace` error handling (for encoding only): the unencodable character is replaced by an appropriate XML character reference.

`codecs.backslashreplace_errors(exception)`

Implements the `backslashreplace` error handling (for encoding only): the unencodable character is replaced by a backslashed escape sequence.

To simplify working with encoded files or stream, the module also defines these utility functions:

`codecs.open(filename, mode[, encoding[, errors[, buffering]]])`

Open an encoded file using the given `mode` and return a wrapped version providing transparent encoding/decoding. The default file mode is `'r'` meaning to open the file in read mode.

Note: The wrapped version will only accept the object format defined by the codecs, i.e. Unicode objects for most built-in codecs. Output is also codec-dependent and will usually be Unicode as well.

Note: Files are always opened in binary mode, even if no binary mode was specified. This is done to avoid data loss due to encodings using 8-bit values. This means that no automatic conversion of `'\n'` is done on reading and

writing.

encoding specifies the encoding which is to be used for the file.

errors may be given to define the error handling. It defaults to 'strict' which causes a *ValueError* to be raised in case an encoding error occurs.

buffering has the same meaning as for the built-in *open()* function. It defaults to line buffered.

`codecs.EncodedFile` (*file*, *input*[, *output*[, *errors*]])

Return a wrapped version of file which provides transparent encoding translation.

Strings written to the wrapped file are interpreted according to the given *input* encoding and then written to the original file as strings using the *output* encoding. The intermediate encoding will usually be Unicode but depends on the specified codecs.

If *output* is not given, it defaults to *input*.

errors may be given to define the error handling. It defaults to 'strict', which causes *ValueError* to be raised in case an encoding error occurs.

`codecs.iterencode` (*iterable*, *encoding*[, *errors*])

Uses an incremental encoder to iteratively encode the input provided by *iterable*. This function is a *generator*. *errors* (as well as any other keyword argument) is passed through to the incremental encoder.

New in version 2.5.

`codecs.iterdecode` (*iterable*, *encoding*[, *errors*])

Uses an incremental decoder to iteratively decode the input provided by *iterable*. This function is a *generator*. *errors* (as well as any other keyword argument) is passed through to the incremental decoder.

New in version 2.5.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

```
codecs.BOM
codecs.BOM_BE
codecs.BOM_LE
codecs.BOM_UTF8
codecs.BOM_UTF16
codecs.BOM_UTF16_BE
codecs.BOM_UTF16_LE
codecs.BOM_UTF32
codecs.BOM_UTF32_BE
codecs.BOM_UTF32_LE
```

These constants define various encodings of the Unicode byte order mark (BOM) used in UTF-16 and UTF-32 data streams to indicate the byte order used in the stream or file and in UTF-8 as a Unicode signature. *BOM_UTF16* is either *BOM_UTF16_BE* or *BOM_UTF16_LE* depending on the platform's native byte order, *BOM* is an alias for *BOM_UTF16*, *BOM_LE* for *BOM_UTF16_LE* and *BOM_BE* for *BOM_UTF16_BE*. The others represent the BOM in UTF-8 and UTF-32 encodings.

7.8.1 Codec Base Classes

The *codecs* module defines a set of base classes which define the interface and can also be used to easily write your own codecs for use in Python.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols.

The `Codec` class defines the interface for stateless encoders/decoders.

To simplify and standardize error handling, the `encode()` and `decode()` methods may implement different error handling schemes by providing the `errors` string argument. The following string values are defined and implemented by all standard Python codecs:

| Value | Meaning |
|---------------------|---|
| 'strict' | Raise <code>UnicodeError</code> (or a subclass); this is the default. |
| 'ignore' | Ignore the character and continue with the next. |
| 'replace' | Replace with a suitable replacement character; Python will use the official U+FFFD REPLACEMENT CHARACTER for the built-in Unicode codecs on decoding and '?' on encoding. |
| 'xmlcharrefreplace' | Replace with the appropriate XML character reference (only for encoding). |
| 'backslashreplace' | Replace with backslashed escape sequences (only for encoding). |

The set of allowed values can be extended via `register_error()`.

Codec Objects

The `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder:

`Codec.encode(input[, errors])`

Encodes the object *input* and returns a tuple (output object, length consumed). While codecs are not restricted to use with Unicode, in a Unicode context, encoding converts a Unicode object to a plain string using a particular character set encoding (e.g., cp1252 or iso-8859-1).

errors defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamWriter` for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

`Codec.decode(input[, errors])`

Decodes the object *input* and returns a tuple (output object, length consumed). In a Unicode context, decoding converts a plain string encoded using a particular character set encoding to a Unicode object.

input must be an object which provides the `bf_getreadbuf` buffer slot. Python strings, buffer objects and memory mapped files are examples of objects providing this slot.

errors defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamReader` for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

The `IncrementalEncoder` and `IncrementalDecoder` classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the `encode()/decode()` method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the `encode()/decode()` method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

IncrementalEncoder Objects

New in version 2.5.

The *IncrementalEncoder* class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

class `codecs.IncrementalEncoder` (*errors*)

Constructor for an *IncrementalEncoder* instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalEncoder* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined:

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character
- 'xmlcharrefreplace' Replace with the appropriate XML character reference
- 'backslashreplace' Replace with backslashed escape sequences.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalEncoder* object.

The set of allowed values for the *errors* argument can be extended with *register_error()*.

encode (*object* [, *final*])

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to *encode()* *final* must be true (the default is false).

reset ()

Reset the encoder to the initial state.

IncrementalDecoder Objects

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

class `codecs.IncrementalDecoder` (*errors*)

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined:

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

The set of allowed values for the *errors* argument can be extended with *register_error()*.

decode (*object* [, *final*])

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

reset ()

Reset the decoder to the initial state.

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

StreamWriter Objects

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

class `codecs.StreamWriter` (*stream* [, *errors*])

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

stream must be a file-like object open for writing binary data.

The *StreamWriter* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined:

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character
- 'xmlcharrefreplace' Replace with the appropriate XML character reference
- 'backslashreplace' Replace with backslashed escape sequences.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamWriter* object.

The set of allowed values for the *errors* argument can be extended with *register_error()*.

write (*object*)

Writes the object's contents encoded to the stream.

writelines (*list*)

Writes the concatenated list of strings to the stream (possibly by reusing the *write()* method).

reset ()

Flushes and resets the codec buffers used for keeping state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the *StreamWriter* must also inherit all other methods and attributes from the underlying stream.

StreamReader Objects

The *StreamReader* class is a subclass of *Codec* and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

class `codecs.StreamReader` (*stream*[, *errors*])

Constructor for a *StreamReader* instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

stream must be a file-like object open for reading (binary) data.

The *StreamReader* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are defined:

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamReader* object.

The set of allowed values for the *errors* argument can be extended with *register_error()*.

read ([*size*[, *chars*[, *firstline*]]])

Decodes data from the stream and returns the resulting object.

chars indicates the number of characters to read from the stream. *read()* will never return more than *chars* characters, but it might return less, if there are not enough characters available.

size indicates the approximate maximum number of bytes to read from the stream for decoding purposes. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. *size* is intended to prevent having to decode huge files in one step.

firstline indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

Changed in version 2.4: *chars* argument added.

Changed in version 2.4.2: *firstline* argument added.

readline ([*size*[, *keepends*]]])

Read one line from the input stream and return the decoded data.

size, if given, is passed as size argument to the stream's *read()* method.

If *keepends* is false line-endings will be stripped from the lines returned.

Changed in version 2.4: *keepends* argument added.

readlines ([*sizehint*[, *keepends*]]])

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's decoder method and are included in the list entries if *keepends* is true.

sizehint, if given, is passed as the *size* argument to the stream's *read()* method.

reset ()

Resets the codec buffers used for keeping state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the *StreamReader* must also inherit all other methods and attributes from the underlying stream.

The next two base classes are included for convenience. They are not needed by the codec registry, but may provide useful in practice.

StreamReaderWriter Objects

The *StreamReaderWriter* allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamReaderWriter` (*stream, Reader, Writer, errors*)

Creates a *StreamReaderWriter* instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the *StreamReader* and *StreamWriter* interface resp. Error handling is done in the same way as defined for the stream readers and writers.

StreamReaderWriter instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

StreamRecoder Objects

The *StreamRecoder* provide a frontend - backend view of encoding data which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamRecoder` (*stream, encode, decode, Reader, Writer, errors*)

Creates a *StreamRecoder* instance which implements a two-way conversion: *encode* and *decode* work on the frontend (the input to *read()* and output of *write()*) while *Reader* and *Writer* work on the backend (reading and writing to the stream).

You can use these objects to do transparent direct recodings from e.g. Latin-1 to UTF-8 and back.

stream must be a file-like object.

encode, *decode* must adhere to the *Codec* interface. *Reader*, *Writer* must be factory functions or classes providing objects of the *StreamReader* and *StreamWriter* interface respectively.

encode and *decode* are needed for the frontend translation, *Reader* and *Writer* for the backend translation. The intermediate format used is determined by the two sets of codecs, e.g. the Unicode codecs will use Unicode as the intermediate encoding.

Error handling is done in the same way as defined for the stream readers and writers.

StreamRecoder instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

7.8.2 Encodings and Unicode

Unicode strings are stored internally as sequences of code points (to be precise as `Py_UNICODE` arrays). Depending on the way Python is compiled (either via `--enable-unicode=ucs2` or `--enable-unicode=ucs4`, with the

former being the default) `Py_UNICODE` is either a 16-bit or 32-bit data type. Once a Unicode object is used outside of CPU and memory, CPU endianness and how these arrays are stored as bytes become an issue. Transforming a unicode object into a sequence of bytes is called encoding and recreating the unicode object from the sequence of bytes is known as decoding. There are many different methods for how this transformation can be done (these methods are also called encodings). The simplest method is to map the code points 0–255 to the bytes 0x0–0xff. This means that a unicode object that contains code points above U+00FF can't be encoded with this method (which is called 'latin-1' or 'iso-8859-1'). `unicode.encode()` will raise a `UnicodeEncodeError` that looks like this: `UnicodeEncodeError: 'latin-1' codec can't encode character u'\u1234' in position 3: ordinal not in range(256)`.

There's another group of encodings (the so called charmap encodings) that choose a different subset of all unicode code points and how these code points are mapped to the bytes 0x0–0xff. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called UTF-32-BE and UTF-32-LE respectively. Their disadvantage is that if e.g. you use UTF-32-BE on a little endian machine you will always have to swap bytes on encoding and decoding. UTF-32 avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a UTF-16 or UTF-32 byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character U+FEFF. This character can be prepended to every UTF-16 or UTF-32 byte sequence. The byte swapped version of this character (0xFFFE) is an illegal character that may not appear in a Unicode text. So when the first character in an UTF-16 or UTF-32 byte sequence appears to be a U+FFFE the bytes have to be swapped on decoding. Unfortunately the character U+FEFF had a second purpose as a ZERO WIDTH NO-BREAK SPACE: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using U+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a Unicode string; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encoding the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

| Range | Encoding |
|---------------------------|-------------------------------------|
| U-00000000 ... U-0000007F | 0xxxxxxx |
| U-00000080 ... U-000007FF | 110xxxxx 10xxxxxx |
| U-00000800 ... U-0000FFFF | 1110xxxx 10xxxxxx 10xxxxxx |
| U-00010000 ... U-0010FFFF | 11110xxx 10xxxxxx 10xxxxxx 10xxxxxx |

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded Unicode string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a Unicode string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python 2.5 calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a

byte sequence: `0xef, 0xbb, 0xbf`) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS
 RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK
 INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a `utf-8-sig` encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the `utf-8-sig` codec will write `0xef, 0xbb, 0xbf` as the first three bytes to the file. On decoding `utf-8-sig` will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

7.8.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

| Codec | Aliases | Languages |
|------------------------|---|---|
| <code>ascii</code> | <code>646</code> , <code>us-ascii</code> | English |
| <code>big5</code> | <code>big5-tw</code> , <code>csbig5</code> | Traditional Chinese |
| <code>big5hkscs</code> | <code>big5-hkscs</code> , <code>hkscs</code> | Traditional Chinese |
| <code>cp037</code> | <code>IBM037</code> , <code>IBM039</code> | English |
| <code>cp424</code> | <code>EBCDIC-CP-HE</code> , <code>IBM424</code> | Hebrew |
| <code>cp437</code> | <code>437</code> , <code>IBM437</code> | English |
| <code>cp500</code> | <code>EBCDIC-CP-BE</code> , <code>EBCDIC-CP-CH</code> , <code>IBM500</code> | Western Europe |
| <code>cp720</code> | | Arabic |
| <code>cp737</code> | | Greek |
| <code>cp775</code> | <code>IBM775</code> | Baltic languages |
| <code>cp850</code> | <code>850</code> , <code>IBM850</code> | Western Europe |
| <code>cp852</code> | <code>852</code> , <code>IBM852</code> | Central and Eastern Europe |
| <code>cp855</code> | <code>855</code> , <code>IBM855</code> | Bulgarian, Byelorussian, Macedonian, Russian, Serbian |
| <code>cp856</code> | | Hebrew |
| <code>cp857</code> | <code>857</code> , <code>IBM857</code> | Turkish |
| <code>cp858</code> | <code>858</code> , <code>IBM858</code> | Western Europe |
| <code>cp860</code> | <code>860</code> , <code>IBM860</code> | Portuguese |

7.8.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated purpose describes the encoding direction.

The following codecs provide unicode-to-str encoding¹ and str-to-unicode decoding², similar to the Unicode text encod-

¹ str objects are also accepted as input in place of unicode objects. They are implicitly converted to unicode by decoding them using the default encoding. If this conversion fails, it may lead to encoding operations raising `UnicodeDecodeError`.

² unicode objects are also accepted as input in place of str objects. They are implicitly converted to str by encoding them using the default encoding.

ings.

| Codec | Aliases | Purpose |
|--------------------|---------|--|
| idna | | Implements RFC 3490 , see also encodings.idna |
| mbcs | dbcs | Windows only: Encode operand according to the ANSI codepage (CP_ACP) |
| palms | | Encoding of PalmOS 3.5 |
| punycode | | Implements RFC 3492 |
| raw_unicode_escape | | Produce a string that is suitable as raw Unicode literal in Python source code |
| rot_13 | rot13 | Returns the Caesar-cypher encryption of the operand |
| undefined | | Raise an exception for all conversions. Can be used as the system encoding if no automatic coercion between byte and Unicode strings is desired. |
| unicode_escape | | Produce a string that is suitable as Unicode literal in Python source code |
| unicode_internal | | Return the internal representation of the operand |

New in version 2.3: The `idna` and `punycode` encodings.

The following codecs provide str-to-str encoding and decoding².

| Codec | Aliases | Purpose | Encoder/decoder |
|---------------|---|---|--|
| base64_codec | base64, base-64 | Convert operand to multiline MIME base64 (the result always includes a trailing '\n') | base64.encodestring() , base64.decodestring() |
| bz2_codec | bz2 | Compress the operand using bz2 | bz2.compress() , bz2.decompress() |
| hex_codec | hex | Convert operand to hexadecimal representation, with two digits per byte | binascii.b2a_hex() , binascii.a2b_hex() |
| quopri_codec | quopri, quoted-printable, quotedprintable | Convert operand to MIME quoted printable | quopri.encode() with <code>quotetabs=True</code> , quopri.decode() |
| string_escape | | Produce a string that is suitable as string literal in Python source code | |
| uu_codec | uu | Convert the operand using uuencode | uu.encode() , uu.decode() |
| zlib_codec | zip, zlib | Compress the operand using gzip | zlib.compress() , zlib.decompress() |

7.8.5 `encodings.idna` — Internationalized Domain Names in Applications

New in version 2.3.

This module implements [RFC 3490](#) (Internationalized Domain Names in Applications) and [RFC 3492](#) (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and [stringprep](#).

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

If this conversion fails, it may lead to decoding operations raising [UnicodeEncodeError](#).

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in [section 3.1](#) (1) of [RFC 3490](#) and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the `socket` module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as `httpplib` and `ftplib`, accept Unicode host names (`httpplib` then also transparently sends an IDNA hostname in the `Host` field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: Applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep(label)`

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is true.

`encodings.idna.ToASCII(label)`

Convert a label to ASCII, as specified in [RFC 3490](#). Use `STD3ASCIIRules` is assumed to be false.

`encodings.idna.ToUnicode(label)`

Convert a label to Unicode, as specified in [RFC 3490](#).

7.8.6 `encodings.utf_8_sig` — UTF-8 codec with BOM signature

New in version 2.5.

This module implements a variant of the UTF-8 codec: On encoding a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). For decoding an optional UTF-8 encoded BOM at the start of the data will be skipped.

7.9 `unicodedata` — Unicode Database

This module provides access to the Unicode Character Database which defines character properties for all Unicode characters. The data in this database is based on the `UnicodeData.txt` file version 5.2.0 which is publicly available from <ftp://ftp.unicode.org/>.

The module uses the same names and symbols as defined by the UnicodeData File Format 5.2.0 (see <http://www.unicode.org/reports/tr44/tr44-4.html>). It defines the following functions:

`unicodedata.lookup(name)`

Look up character by name. If a character with the given name is found, return the corresponding Unicode character. If not found, `KeyError` is raised.

`unicodedata.name(unichr[, default])`

Returns the name assigned to the Unicode character *unichr* as a string. If no name is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.decimal(unichr[, default])`

Returns the decimal value assigned to the Unicode character *unichr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.digit(unichr[, default])`

Returns the digit value assigned to the Unicode character *unichr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

`unicodedata.numeric(unichr[, default])`

Returns the numeric value assigned to the Unicode character *unichr* as float. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

`unicodedata.category(unichr)`

Returns the general category assigned to the Unicode character *unichr* as string.

`unicodedata.bidirectional(unichr)`

Returns the bidirectional class assigned to the Unicode character *unichr* as string. If no such value is defined, an empty string is returned.

`unicodedata.combining(unichr)`

Returns the canonical combining class assigned to the Unicode character *unichr* as integer. Returns 0 if no combining class is defined.

`unicodedata.east_asian_width(unichr)`

Returns the east asian width assigned to the Unicode character *unichr* as string.

New in version 2.4.

`unicodedata.mirrored(unichr)`

Returns the mirrored property assigned to the Unicode character *unichr* as integer. Returns 1 if the character has been identified as a “mirrored” character in bidirectional text, 0 otherwise.

`unicodedata.decomposition(unichr)`

Returns the character decomposition mapping assigned to the Unicode character *unichr* as string. An empty string is returned in case no such mapping is defined.

`unicodedata.normalize(form, unistr)`

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are ‘NFC’, ‘NFKC’, ‘NFD’, and ‘NFKD’.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U+00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U+0043 (LATIN CAPITAL LETTER C) U+0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U+2160 (ROMAN NUMERAL ONE) is really the same thing as U+0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

New in version 2.3.

In addition, the module exposes the following constant:

`unicodedata.unidata_version`

The version of the Unicode database used in this module.

New in version 2.3.

`unicodedata.ucd_3_2_0`

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

New in version 2.5.

Examples:

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
u'{'
>>> unicodedata.name(u'/')
'SOLIDUS'
>>> unicodedata.decimal(u'9')
9
>>> unicodedata.decimal(u'a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category(u'A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional(u'\u0660') # 'A'rabic, 'N'umber
'AN'
```

7.10 stringprep — Internet String Preparation

New in version 2.3.

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for “equality”. Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of “printable” characters.

RFC 3454 defines a procedure for “preparing” Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the `stringprep` procedure are part of the profile. One example of a `stringprep` profile is `nameprep`, which is used for internationalized domain names.

The module `stringprep` only exposes the tables from RFC 3454. As these tables would be very large to represent them as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the `mkstringprep.py` utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, `stringprep` provides the “characteristic function”, i.e. a function that returns true if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all functions available in the module.

`stringprep.in_table_a1` (*code*)

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

`stringprep.in_table_b1` (*code*)

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

`stringprep.map_table_b2 (code)`

Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

`stringprep.map_table_b3 (code)`

Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

`stringprep.in_table_c11 (code)`

Determine whether *code* is in tableC.1.1 (ASCII space characters).

`stringprep.in_table_c12 (code)`

Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

`stringprep.in_table_c11_c12 (code)`

Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

`stringprep.in_table_c21 (code)`

Determine whether *code* is in tableC.2.1 (ASCII control characters).

`stringprep.in_table_c22 (code)`

Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

`stringprep.in_table_c21_c22 (code)`

Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

`stringprep.in_table_c3 (code)`

Determine whether *code* is in tableC.3 (Private use).

`stringprep.in_table_c4 (code)`

Determine whether *code* is in tableC.4 (Non-character code points).

`stringprep.in_table_c5 (code)`

Determine whether *code* is in tableC.5 (Surrogate codes).

`stringprep.in_table_c6 (code)`

Determine whether *code* is in tableC.6 (Inappropriate for plain text).

`stringprep.in_table_c7 (code)`

Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

`stringprep.in_table_c8 (code)`

Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

`stringprep.in_table_c9 (code)`

Determine whether *code* is in tableC.9 (Tagging characters).

`stringprep.in_table_d1 (code)`

Determine whether *code* is in tableD.1 (Characters with bidirectional property “R” or “AL”).

`stringprep.in_table_d2 (code)`

Determine whether *code* is in tableD.2 (Characters with bidirectional property “L”).

7.11 `fpformat` — Floating point conversions

Deprecated since version 2.6: The `fpformat` module has been removed in Python 3.

The `fpformat` module defines functions for dealing with floating point numbers representations in 100% pure Python.

Note: This module is unnecessary: everything here can be done using the `%` string interpolation operator described in the *String Formatting Operations* section.

The `fpformat` module defines the following functions and an exception:

`fpformat.fix(x, digs)`

Format *x* as `[-]ddd.ddd` with *digs* digits after the point and at least one digit before. If *digs* \leq 0, the decimal point is suppressed.

x can be either a number or a string that looks like one. *digs* is an integer.

Return value is a string.

`fpformat.sci(x, digs)`

Format *x* as `[-]d.dddE[+-]ddd` with *digs* digits after the point and exactly one digit before. If *digs* \leq 0, one digit is kept and the point is suppressed.

x can be either a real number, or a string that looks like one. *digs* is an integer.

Return value is a string.

exception `fpformat.NotANumber`

Exception raised when a string passed to `fix()` or `sci()` as the *x* parameter does not look like a number. This is a subclass of `ValueError` when the standard exceptions are strings. The exception value is the improperly formatted string that caused the exception to be raised.

Example:

```
>>> import fpformat
>>> fpformat.fix(1.23, 1)
'1.2'
```

DATA TYPES

The modules described in this chapter provide a variety of specialized data types such as dates and times, fixed-type arrays, heap queues, synchronized queues, and sets.

Python also provides some built-in data types, in particular, *dict*, *list*, *set* (which along with *frozenset*, replaces the deprecated *sets* module), and *tuple*. The *str* class can be used to handle binary data and 8-bit text, and the *unicode* class to handle Unicode text.

The following modules are documented in this chapter:

8.1 *datetime* — Basic date and time types

New in version 2.3.

The *datetime* module supplies classes for manipulating dates and times in both simple and complex ways. While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation. For related functionality, see also the *time* and *calendar* modules.

There are two kinds of date and time objects: “naive” and “aware”.

An aware object has sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, to locate itself relative to other aware objects. An aware object is used to represent a specific moment in time that is not open to interpretation¹.

A naive object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other timezone is purely up to the program, just like it’s up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, *datetime* and *time* objects have an optional time zone information attribute, *tzinfo*, that can be set to an instance of a subclass of the abstract *tzinfo* class. These *tzinfo* objects capture information about the offset from UTC time, the time zone name, and whether Daylight Saving Time is in effect. Note that no concrete *tzinfo* classes are supplied by the *datetime* module. Supporting timezones at whatever level of detail is required is up to the application. The rules for time adjustment across the world are more political than rational, and there is no standard suitable for every application.

The *datetime* module exports the following constants:

`datetime.MINYEAR`

The smallest year number allowed in a *date* or *datetime* object. *MINYEAR* is 1.

`datetime.MAXYEAR`

The largest year number allowed in a *date* or *datetime* object. *MAXYEAR* is 9999.

¹ If, that is, we ignore the effects of Relativity

See also:

Module `calendar` General calendar related functions.

Module `time` Time access and conversions.

8.1.1 Available Types

class `datetime.date`

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: `year`, `month`, and `day`.

class `datetime.time`

An idealized time, independent of any particular day, assuming that every day has exactly 24*60*60 seconds (there is no notion of “leap seconds” here). Attributes: `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

class `datetime.datetime`

A combination of a date and a time. Attributes: `year`, `month`, `day`, `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

class `datetime.timedelta`

A duration expressing the difference between two `date`, `time`, or `datetime` instances to microsecond resolution.

class `datetime.tzinfo`

An abstract base class for time zone information objects. These are used by the `datetime` and `time` classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

Objects of these types are immutable.

Objects of the `date` type are always naive.

An object of type `time` or `datetime` may be naive or aware. A `datetime` object `d` is aware if `d.tzinfo` is not `None` and `d.tzinfo.utcoffset(d)` does not return `None`. If `d.tzinfo` is `None`, or if `d.tzinfo` is not `None` but `d.tzinfo.utcoffset(d)` returns `None`, `d` is naive. A `time` object `t` is aware if `t.tzinfo` is not `None` and `t.tzinfo.utcoffset(None)` does not return `None`. Otherwise, `t` is naive.

The distinction between naive and aware doesn’t apply to `timedelta` objects.

Subclass relationships:

```
object
  timedelta
  tzinfo
  time
  date
    datetime
```

8.1.2 `timedelta` Objects

A `timedelta` object represents a duration, the difference between two dates or times.

class `datetime.timedelta` (`[days[, seconds[, microseconds[, milliseconds[, minutes[, hours[, weeks]]]]]`)

All arguments are optional and default to 0. Arguments may be ints, longs, or floats, and may be positive or negative.

Only `days`, `seconds` and `microseconds` are stored internally. Arguments are converted to those units:

- A millisecond is converted to 1000 microseconds.
- A minute is converted to 60 seconds.
- An hour is converted to 3600 seconds.
- A week is converted to 7 days.

and days, seconds and microseconds are then normalized so that the representation is unique, with

- $0 \leq \text{microseconds} < 1000000$
- $0 \leq \text{seconds} < 3600 \times 24$ (the number of seconds in one day)
- $-999999999 \leq \text{days} \leq 999999999$

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of days lies outside the indicated range, `OverflowError` is raised.

Note that normalization of negative values may be surprising at first. For example,

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

Class attributes are:

`timedelta.min`

The most negative `timedelta` object, `timedelta(-999999999)`.

`timedelta.max`

The most positive `timedelta` object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

The smallest possible difference between non-equal `timedelta` objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max > -timedelta.min`. `-timedelta.max` is not representable as a `timedelta` object.

Instance attributes (read-only):

| Attribute | Value |
|---------------------------|--|
| <code>days</code> | Between -999999999 and 999999999 inclusive |
| <code>seconds</code> | Between 0 and 86399 inclusive |
| <code>microseconds</code> | Between 0 and 999999 inclusive |

Supported operations:

| Operation | Result |
|--|--|
| <code>t1 = t2 + t3</code> | Sum of <i>t2</i> and <i>t3</i> . Afterwards <i>t1-t2</i> == <i>t3</i> and <i>t1-t3</i> == <i>t2</i> are true. (1) |
| <code>t1 = t2 - t3</code> | Difference of <i>t2</i> and <i>t3</i> . Afterwards <i>t1</i> == <i>t2 - t3</i> and <i>t2</i> == <i>t1 + t3</i> are true. (1) |
| <code>t1 = t2 * i</code> or <code>t1 = i * t2</code> | Delta multiplied by an integer or long. Afterwards <i>t1</i> // <i>i</i> == <i>t2</i> is true, provided <i>i</i> != 0. |
| | In general, <i>t1</i> * <i>i</i> == <i>t1</i> * (<i>i</i> -1) + <i>t1</i> is true. (1) |
| <code>t1 = t2 // i</code> | The floor is computed and the remainder (if any) is thrown away. (3) |
| <code>+t1</code> | Returns a <i>timedelta</i> object with the same value. (2) |
| <code>-t1</code> | equivalent to <i>timedelta(-t1.days, -t1.seconds, -t1.microseconds)</i> , and to <i>t1</i> * -1. (1)(4) |
| <code>abs(t)</code> | equivalent to <i>+t</i> when <i>t.days</i> >= 0, and to <i>-t</i> when <i>t.days</i> < 0. (2) |
| <code>str(t)</code> | Returns a string in the form [D day[s],][H]H:MM:SS[.UUUUUU], where D is negative for negative <i>t</i> . (5) |
| <code>repr(t)</code> | Returns a string in the form <i>datetime.timedelta(D[, S[, U]])</i> , where D is negative for negative <i>t</i> . (5) |

Notes:

- (1) This is exact, but may overflow.
- (2) This is exact, and cannot overflow.
- (3) Division by 0 raises *ZeroDivisionError*.
- (4) *-timedelta.max* is not representable as a *timedelta* object.
- (5) String representations of *timedelta* objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(-1, 68400)
>>> print(_)
-1 day, 19:00:00
```

In addition to the operations listed above *timedelta* objects support certain additions and subtractions with *date* and *datetime* objects (see below).

Comparisons of *timedelta* objects are supported with the *timedelta* object representing the smaller duration considered to be the smaller *timedelta*. In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a *timedelta* object is compared to an object of a different type, *TypeError* is raised unless the comparison is == or !=. The latter cases return *False* or *True*, respectively.

timedelta objects are *hashable* (usable as dictionary keys), support efficient pickling, and in Boolean contexts, a *timedelta* object is considered to be true if and only if it isn't equal to *timedelta(0)*.

Instance methods:

`timedelta.total_seconds()`

Return the total number of seconds contained in the duration. Equivalent to `(td.microseconds + (td.seconds + td.days * 24 * 3600) * 10**6) / 10**6` computed with true division enabled.

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

New in version 2.7.

Example usage:

```

>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                           minutes=50, seconds=600) # adds up to 365 days
>>> year.total_seconds()
31536000.0
>>> year == another_year
True
>>> ten_years = 10 * year
>>> ten_years, ten_years.days // 365
(datetime.timedelta(3650), 10)
>>> nine_years = ten_years - year
>>> nine_years, nine_years.days // 365
(datetime.timedelta(3285), 9)
>>> three_years = nine_years // 3;
>>> three_years, three_years.days // 365
(datetime.timedelta(1095), 3)
>>> abs(three_years - ten_years) == 2 * three_years + year
True

```

8.1.3 date Objects

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions. January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on. This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book *Calendrical Calculations*, where it’s the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

class `datetime.date` (*year, month, day*)

All arguments are required. Arguments may be ints or longs, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, *ValueError* is raised.

Other constructors, all class methods:

classmethod `date.today()`

Return the current local date. This is equivalent to `date.fromtimestamp(time.time())`.

classmethod `date.fromtimestamp(timestamp)`

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`. This may raise *ValueError*, if the timestamp is out of the range of values supported by the platform `C localtime()` function. It’s common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

classmethod `date.fromordinal(ordinal)`

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. *ValueError* is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date *d*, `date.fromordinal(d.toordinal()) == d`.

Class attributes:

`date.min`

The earliest representable date, `date(MINYEAR, 1, 1)`.

`date.max`

The latest representable date, `date(MAXYEAR, 12, 31)`.

`date.resolution`

The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

`date.year`

Between `MINYEAR` and `MAXYEAR` inclusive.

`date.month`

Between 1 and 12 inclusive.

`date.day`

Between 1 and the number of days in the given month of the given year.

Supported operations:

| Operation | Result |
|--|--|
| <code>date2 = date1 + timedelta</code> | <i>date2</i> is <code>timedelta.days</code> days removed from <i>date1</i> . (1) |
| <code>date2 = date1 - timedelta</code> | Computes <i>date2</i> such that <code>date2 + timedelta == date1</code> . (2) |
| <code>timedelta = date1 - date2</code> | (3) |
| <code>date1 < date2</code> | <i>date1</i> is considered less than <i>date2</i> when <i>date1</i> precedes <i>date2</i> in time. (4) |

Notes:

- (1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days`. `timedelta.seconds` and `timedelta.microseconds` are ignored. `OverflowError` is raised if `date2.year` would be smaller than `MINYEAR` or larger than `MAXYEAR`.
- (2) This isn't quite equivalent to `date1 + (-timedelta)`, because `-timedelta` in isolation can overflow in cases where `date1 - timedelta` does not. `timedelta.seconds` and `timedelta.microseconds` are ignored.
- (3) This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.
- (4) In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`. In order to stop comparison from falling back to the default scheme of comparing object addresses, date comparison normally raises `TypeError` if the other comparand isn't also a `date` object. However, `NotImplemented` is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a `date` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

Dates can be used as dictionary keys. In Boolean contexts, all `date` objects are considered to be true.

Instance methods:

`date.replace(year, month, day)`

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified. For example, if `d == date(2002, 12, 31)`, then `d.replace(day=26) == date(2002, 12, 26)`.

`date.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`. The hours, minutes and seconds are 0, and the DST flag is -1. `d.timetuple()` is equivalent to `time.struct_time((d.year, d.month,`

`d.day, 0, 0, 0, d.weekday(), yday, -1))`, where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

`date.toordinal()`

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any *date* object *d*, `date.fromordinal(d.toordinal()) == d`.

`date.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. For example, `date(2002, 12, 4).weekday() == 2`, a Wednesday. See also *isoweekday()*.

`date.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also *weekday()*, *isocalendar()*.

`date.isocalendar()`

Return a 3-tuple, (ISO year, ISO week number, ISO weekday).

The ISO calendar is a widely used variant of the Gregorian calendar. See <https://www.staff.science.uu.nl/~gent0113/calendar/isocalendar.htm> for a good explanation.

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004, so that `date(2003, 12, 29).isocalendar() == (2004, 1, 1)` and `date(2004, 1, 4).isocalendar() == (2004, 1, 7)`.

`date.isoformat()`

Return a string representing the date in ISO 8601 format, 'YYYY-MM-DD'. For example, `date(2002, 12, 4).isoformat() == '2002-12-04'`.

`date.__str__()`

For a date *d*, `str(d)` is equivalent to `d.isoformat()`.

`date.ctime()`

Return a string representing the date, for example `date(2002, 12, 4).ctime() == 'Wed Dec 4 00:00:00 2002'`. `d.ctime()` is equivalent to `time.ctime(time.mktime(d.timetuple()))` on platforms where the native C `ctime()` function (which *time.ctime()* invokes, but which *date.ctime()* does not invoke) conforms to the C standard.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. For a complete list of formatting directives, see section *strftime() and strptime() Behavior*.

`date.__format__(format)`

Same as *date.strftime()*. This makes it possible to specify a format string for a *date* object when using *str.format()*. See section *strftime() and strptime() Behavior*.

Example of counting days to an event:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
```

(continues on next page)

(continued from previous page)

```

True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202

```

Example of working with `date`:

```

>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)
>>> t = d.timetuple()
>>> for i in t:
...     print i
2002          # year
3             # month
11            # day
0
0
0
0             # weekday (0 = Monday)
70            # 70th day in the year
-1
>>> ic = d.isocalendar()
>>> for i in ic:
...     print i
2002          # ISO year
11            # ISO week number
1             # ISO day number ( 1 = Monday )
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'

```

8.1.4 datetime Objects

A `datetime` object is a single object containing all the information from a `date` object and a `time` object. Like a `date` object, `datetime` assumes the current Gregorian calendar extended in both directions; like a `time` object, `datetime` assumes there are exactly 3600*24 seconds in every day.

Constructor:

```
class datetime.datetime (year, month, day[, hour[, minute[, second[, microsecond[, tzinfo]]]]])
```

The year, month and day arguments are required. `tzinfo` may be `None`, or an instance of a `tzinfo` subclass. The remaining arguments may be ints or longs, in the following ranges:

- MINYEAR <= year <= MAXYEAR

- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`
- `0 <= hour < 24`
- `0 <= minute < 60`
- `0 <= second < 60`
- `0 <= microsecond < 1000000`

If an argument outside those ranges is given, `ValueError` is raised.

Other constructors, all class methods:

classmethod `datetime.today()`

Return the current local datetime, with `tzinfo` `None`. This is equivalent to `datetime.fromtimestamp(time.time())`. See also `now()`, `fromtimestamp()`.

classmethod `datetime.now([tz])`

Return the current local date and time. If optional argument `tz` is `None` or not specified, this is like `today()`, but, if possible, supplies more precision than can be gotten from going through a `time.time()` timestamp (for example, this may be possible on platforms supplying the C `gettimeofday()` function).

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the current date and time are converted to `tz`'s time zone. In this case the result is equivalent to `tz.fromutc(datetime.utcnow()).replace(tzinfo=tz)`. See also `today()`, `utcnow()`.

classmethod `datetime.utcnow()`

Return the current UTC date and time, with `tzinfo` `None`. This is like `now()`, but returns the current UTC date and time, as a naive `datetime` object. See also `now()`.

classmethod `datetime.fromtimestamp(timestamp[, tz])`

Return the local date and time corresponding to the POSIX timestamp, such as is returned by `time.time()`. If optional argument `tz` is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned `datetime` object is naive.

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the timestamp is converted to `tz`'s time zone. In this case the result is equivalent to `tz.fromutc(datetime.utcfromtimestamp(timestamp)).replace(tzinfo=tz)`.

`fromtimestamp()` may raise `ValueError`, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical `datetime` objects. See also `utcfromtimestamp()`.

classmethod `datetime.utcfromtimestamp(timestamp)`

Return the UTC `datetime` corresponding to the POSIX timestamp, with `tzinfo` `None`. This may raise `ValueError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function. It's common for this to be restricted to years in 1970 through 2038. See also `fromtimestamp()`.

classmethod `datetime.fromordinal(ordinal)`

Return the `datetime` corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless `1 <= ordinal <= datetime.max.toordinal()`. The hour, minute, second and microsecond of the result are all 0, and `tzinfo` is `None`.

classmethod `datetime.combine(date, time)`

Return a new `datetime` object whose date components are equal to the given `date` object's, and whose time components and `tzinfo` attributes are equal to the given `time` object's. For any `datetime` object `d`, `d ==`

`datetime.combine(d.date(), d.timetz())`. If `date` is a *datetime* object, its time components and *tzinfo* attributes are ignored.

classmethod `datetime.strptime(date_string, format)`

Return a *datetime* corresponding to *date_string*, parsed according to *format*. This is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`. *ValueError* is raised if the *date_string* and *format* can't be parsed by *time.strptime()* or if it returns a value which isn't a time tuple. For a complete list of formatting directives, see section *strptime() and strftime() Behavior*.

New in version 2.5.

Class attributes:

`datetime.min`

The earliest representable *datetime*, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

The latest representable *datetime*, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

The smallest possible difference between non-equal *datetime* objects, `timedelta(microseconds=1)`.

Instance attributes (read-only):

`datetime.year`

Between *MINYEAR* and *MAXYEAR* inclusive.

`datetime.month`

Between 1 and 12 inclusive.

`datetime.day`

Between 1 and the number of days in the given month of the given year.

`datetime.hour`

In range (24).

`datetime.minute`

In range (60).

`datetime.second`

In range (60).

`datetime.microsecond`

In range (1000000).

`datetime.tzinfo`

The object passed as the *tzinfo* argument to the *datetime* constructor, or *None* if none was passed.

Supported operations:

| Operation | Result |
|--|---|
| <code>datetime2 = datetime1 + timedelta</code> | (1) |
| <code>datetime2 = datetime1 - timedelta</code> | (2) |
| <code>timedelta = datetime1 - datetime2</code> | (3) |
| <code>datetime1 < datetime2</code> | Compares <i>datetime</i> to <i>datetime</i> . (4) |

- (1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same *tzinfo* attribute as the input *datetime*, and `datetime2 - datetime1 == timedelta` after. *OverflowError* is raised if `datetime2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*. Note that no time zone adjustments are done even if the input is an aware object.

- (2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same `tzinfo` attribute as the input `datetime`, and no time zone adjustments are done even if the input is aware. This isn't quite equivalent to `datetime1 + (-timedelta)`, because `-timedelta` in isolation can overflow in cases where `datetime1 - timedelta` does not.

- (3) Subtraction of a `datetime` from a `datetime` is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, `TypeError` is raised.

If both are naive, or both are aware and have the same `tzinfo` attribute, the `tzinfo` attributes are ignored, and the result is a `timedelta` object `t` such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different `tzinfo` attributes, `a-b` acts as if `a` and `b` were first converted to naive UTC datetimes first. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

- (4) `datetime1` is considered less than `datetime2` when `datetime1` precedes `datetime2` in time.

If one comparand is naive and the other is aware, `TypeError` is raised. If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base datetimes are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

Note: In order to stop comparison from falling back to the default scheme of comparing object addresses, `datetime` comparison normally raises `TypeError` if the other comparand isn't also a `datetime` object. However, `NotImplemented` is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a `datetime` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

`datetime` objects can be used as dictionary keys. In Boolean contexts, all `datetime` objects are considered to be true.

Instance methods:

`datetime.date()`

Return `date` object with same year, month and day.

`datetime.time()`

Return `time` object with same hour, minute, second and microsecond. `tzinfo` is `None`. See also method `timetz()`.

`datetime.timetz()`

Return `time` object with same hour, minute, second, microsecond, and `tzinfo` attributes. See also method `time()`.

`datetime.replace([year[, month[, day[, hour[, minute[, second[, microsecond[, tzinfo]]]]]]])`

Return a `datetime` with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `datetime` from an aware `datetime` with no conversion of date and time data.

`datetime.astimezone(tz)`

Return a `datetime` object with new `tzinfo` attribute `tz`, adjusting the date and time data so the result is the same UTC time as `self`, but in `tz`'s local time.

`tz` must be an instance of a `tzinfo` subclass, and its `utcoffset()` and `dst()` methods must not return `None`. `self` must be aware (`self.tzinfo` must not be `None`, and `self.utcoffset()` must not return `None`).

If `self.tzinfo` is `tz`, `self.astimezone(tz)` is equal to `self`: no adjustment of date or time data is performed. Else the result is local time in time zone `tz`, representing the same UTC time as `self`: after `astz = dt.astimezone(tz)`, `astz - astz.utcoffset()` will usually have the same date and time data as `dt - dt.utcoffset()`. The discussion of class `tzinfo` explains the cases at Daylight Saving Time transition boundaries where this cannot be achieved (an issue only if `tz` models both standard and daylight time).

If you merely want to attach a time zone object `tz` to a datetime `dt` without adjustment of date and time data, use `dt.replace(tzinfo=tz)`. If you merely want to remove the time zone object from an aware datetime `dt` without conversion of date and time data, use `dt.replace(tzinfo=None)`.

Note that the default `tzinfo.fromutc()` method can be overridden in a `tzinfo` subclass to affect the result returned by `astimezone()`. Ignoring error cases, `astimezone()` acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new time zone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

`datetime.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(self)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`datetime.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(self)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`datetime.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(self)`, raises an exception if the latter doesn't return `None` or a string object,

`datetime.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`. `d.timetuple()` is equivalent to `time.struct_time((d.year, d.month, d.day, d.hour, d.minute, d.second, d.weekday(), yday, dst))`, where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st. The `tm_isdst` flag of the result is set according to the `dst()` method: `tzinfo` is `None` or `dst()` returns `None`, `tm_isdst` is set to -1; else if `dst()` returns a non-zero value, `tm_isdst` is set to 1; else `tm_isdst` is set to 0.

`datetime.utctimetuple()`

If `datetime` instance `d` is naive, this is the same as `d.timetuple()` except that `tm_isdst` is forced to 0 regardless of what `d.dst()` returns. DST is never in effect for a UTC time.

If `d` is aware, `d` is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to 0. Note that the result's `tm_year` member may be `MINYEAR-1` or `MAXYEAR+1`, if `d.year` was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

`datetime.toordinal()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

`datetime.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also `isoweekday()`.

`datetime.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also `weekday()`, `isocalendar()`.

`datetime.isocalendar()`

Return a 3-tuple, (ISO year, ISO week number, ISO weekday). The same as `self.date().isocalendar()`.

`datetime.isoformat([sep])`

Return a string representing the date and time in ISO 8601 format, YYYY-MM-DDTHH:MM:SS.mmmmmmm or, if `microsecond` is 0, YYYY-MM-DDTHH:MM:SS

If `utcoffset()` does not return None, a 6-character string is appended, giving the UTC offset in (signed) hours and minutes: YYYY-MM-DDTHH:MM:SS.mmmmmmm+HH:MM or, if `microsecond` is 0 YYYY-MM-DDTHH:MM:SS+HH:MM

The optional argument `sep` (default 'T') is a one-character separator, placed between the date and time portions of the result. For example,

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     def utcoffset(self, dt): return timedelta(minutes=-399)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
```

`datetime.__str__()`

For a `datetime` instance `d`, `str(d)` is equivalent to `d.isoformat(' ')`.

`datetime.ctime()`

Return a string representing the date and time, for example `datetime(2002, 12, 4, 20, 30, 40).ctime() == 'Wed Dec 4 20:30:40 2002'`. `d.ctime()` is equivalent to `time.ctime(time.mktime(d.timetuple()))` on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `datetime.ctime()` does not invoke) conforms to the C standard.

`datetime.strftime(format)`

Return a string representing the date and time, controlled by an explicit format string. For a complete list of formatting directives, see section *strftime() and strptime() Behavior*.

`datetime.__format__(format)`

Same as `datetime.strftime()`. This makes it possible to specify a format string for a `datetime` object when using `str.format()`. See section *strftime() and strptime() Behavior*.

Examples of working with datetime objects:

```
>>> from datetime import datetime, date, time
>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)
>>> # Using datetime.now() or datetime.utcnow()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043) # GMT +1
>>> datetime.utcnow()
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060)
>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)
```

(continues on next page)

(continued from previous page)

```

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print it
...
2006      # year
11        # month
21        # day
16        # hour
30        # minute
0         # second
1         # weekday (0 = Monday)
325       # number of days since 1st January
-1        # dst - method tzinfo.dst() returned None
>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print it
...
2006      # ISO year
47        # ISO week
2         # ISO weekday
>>> # Formatting datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day",
↪ "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'

```

Using datetime with tzinfo:

```

>>> from datetime import timedelta, datetime, tzinfo
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1) + self.dst(dt)
...     def dst(self, dt):
...         # DST starts last Sunday in March
...         d = datetime(dt.year, 4, 1) # ends last Sunday in October
...         self.dston = d - timedelta(days=d.weekday() + 1)
...         d = datetime(dt.year, 11, 1)
...         self.dstoff = d - timedelta(days=d.weekday() + 1)
...         if self.dston <= dt.replace(tzinfo=None) < self.dstoff:
...             return timedelta(hours=1)
...         else:
...             return timedelta(0)
...     def tzname(self, dt):
...         return "GMT +1"
...
>>> class GMT2(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=2) + self.dst(dt)
...     def dst(self, dt):
...         d = datetime(dt.year, 4, 1)
...         self.dston = d - timedelta(days=d.weekday() + 1)
...         d = datetime(dt.year, 11, 1)
...         self.dstoff = d - timedelta(days=d.weekday() + 1)
...         if self.dston <= dt.replace(tzinfo=None) < self.dstoff:

```

(continues on next page)

(continued from previous page)

```

...         return timedelta(hours=1)
...     else:
...         return timedelta(0)
...     def tzname(self, dt):
...         return "GMT +2"
...
>>> gmt1 = GMT1()
>>> # Daylight Saving Time
>>> dt1 = datetime(2006, 11, 21, 16, 30, tzinfo=gmt1)
>>> dt1.dst()
datetime.timedelta(0)
>>> dt1.utcoffset()
datetime.timedelta(0, 3600)
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=gmt1)
>>> dt2.dst()
datetime.timedelta(0, 3600)
>>> dt2.utcoffset()
datetime.timedelta(0, 7200)
>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(GMT2())
>>> dt3      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 14, 0, tzinfo=<GMT2 object at 0x...>)
>>> dt2      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=<GMT1 object at 0x...>)
>>> dt2.utctimetuple() == dt3.utctimetuple()
True

```

8.1.5 time Objects

A time object represents a (local) time of day, independent of any particular day, and subject to adjustment via a *tzinfo* object.

class `datetime.time([hour[, minute[, second[, microsecond[, tzinfo]]]])`

All arguments are optional. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments may be ints or longs, in the following ranges:

- 0 <= hour < 24
- 0 <= minute < 60
- 0 <= second < 60
- 0 <= microsecond < 1000000.

If an argument outside those ranges is given, *ValueError* is raised. All default to 0 except *tzinfo*, which defaults to *None*.

Class attributes:

`time.min`

The earliest representable *time*, `time(0, 0, 0, 0)`.

`time.max`

The latest representable *time*, `time(23, 59, 59, 999999)`.

`time.resolution`

The smallest possible difference between non-equal *time* objects, `timedelta(microseconds=1)`, although note that arithmetic on *time* objects is not supported.

Instance attributes (read-only):

`time.hour`
In range (24).

`time.minute`
In range (60).

`time.second`
In range (60).

`time.microsecond`
In range (1000000).

`time.tzinfo`
The object passed as the `tzinfo` argument to the `time` constructor, or `None` if none was passed.

Supported operations:

- comparison of `time` to `time`, where *a* is considered less than *b* when *a* precedes *b* in time. If one comparand is naive and the other is aware, `TypeError` is raised. If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`). In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a `time` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.
- hash, use as dict key
- efficient pickling
- in Boolean contexts, a `time` object is considered to be true if and only if, after converting it to minutes and subtracting `utcoffset()` (or 0 if that's `None`), the result is non-zero.

Instance methods:

`time.replace([hour[, minute[, second[, microsecond[, tzinfo]]]])`
Return a `time` with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `time` from an aware `time`, without conversion of the time data.

`time.isoformat()`
Return a string representing the time in ISO 8601 format, HH:MM:SS.mmmmmm or, if `self.microsecond` is 0, HH:MM:SS. If `utcoffset()` does not return `None`, a 6-character string is appended, giving the UTC offset in (signed) hours and minutes: HH:MM:SS.mmmmmm+HH:MM or, if `self.microsecond` is 0, HH:MM:SS+HH:MM

`time.__str__()`
For a time *t*, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`
Return a string representing the time, controlled by an explicit format string. For a complete list of formatting directives, see section *strftime() and strptime() Behavior*.

`time.__format__(format)`
Same as `time.strftime()`. This makes it possible to specify a format string for a `time` object when using `str.format()`. See section *strftime() and strptime() Behavior*.

`time.utcoffset()`
If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`time.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`time.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return `None` or a string object.

Example:

```
>>> from datetime import time, tzinfo, timedelta
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self, dt):
...         return "Europe/Prague"
...
>>> t = time(12, 10, 30, tzinfo=GMT1())
>>> t                                     # doctest: +ELLIPSIS
datetime.time(12, 10, 30, tzinfo=<GMT1 object at 0x...>)
>>> gmt = GMT1()
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'Europe/Prague'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 Europe/Prague'
>>> 'The {} is {:%H:%M}'.format("time", t)
'The time is 12:10.'
```

8.1.6 tzinfo Objects

class `datetime.tzinfo`

This is an abstract base class, meaning that this class should not be instantiated directly. You need to derive a concrete subclass, and (at least) supply implementations of the standard `tzinfo` methods needed by the `datetime` methods you use. The `datetime` module does not supply any concrete subclasses of `tzinfo`.

An instance of (a concrete subclass of) `tzinfo` can be passed to the constructors for `datetime` and `time` objects. The latter objects view their attributes as being in local time, and the `tzinfo` object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

Special requirement for pickling: A `tzinfo` subclass must have an `__init__()` method that can be called with no arguments, else it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of `tzinfo` may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

`tzinfo.utcoffset(self, dt)`

Return offset of local time from UTC, in minutes east of UTC. If local time is west of UTC, this should be negative. Note that this is intended to be the total offset from UTC; for example, if a `tzinfo` object represents both time zone and DST adjustments, `utcoffset()` should return their sum. If the UTC offset isn't known, return `None`.

Else the value returned must be a `timedelta` object specifying a whole number of minutes in the range -1439 to 1439 inclusive ($1440 = 24 \times 60$; the magnitude of the offset must be less than one day). Most implementations of `utcoffset()` will probably look like one of these two:

```
return CONSTANT          # fixed-offset class
return CONSTANT + self.dst(dt) # daylight-aware class
```

If `utcoffset()` does not return `None`, `dst()` should not return `None` either.

The default implementation of `utcoffset()` raises `NotImplementedError`.

`tzinfo.dst(self, dt)`

Return the daylight saving time (DST) adjustment, in minutes east of UTC, or `None` if DST information isn't known. Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a `timedelta` object (see `utcoffset()` for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by `utcoffset()`, so there's no need to consult `dst()` unless you're interested in obtaining DST info separately. For example, `datetime.timetuple()` calls its `tzinfo` attribute's `dst()` method to determine how the `tm_isdst` flag should be set, and `tzinfo.fromutc()` calls `dst()` to account for DST changes when crossing time zones.

An instance `tz` of a `tzinfo` subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every `datetime dt` with `dt.tzinfo == tz`. For sane `tzinfo` subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of `datetime.astimezone()` relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a `tzinfo` subclass cannot guarantee this, it may be able to override the default implementation of `tzinfo.fromutc()` to work correctly with `astimezone()` regardless.

Most implementations of `dst()` will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class: doesn't account for DST
    return timedelta(0)
```

or

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time. Then

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of `dst()` raises `NotImplementedError`.

`tzinfo.tzname(self, dt)`

Return the time zone name corresponding to the `datetime` object `dt`, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, "GMT", "UTC", "-500", "-5:00", "EDT", "US/Eastern", "America/New York" are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some `tzinfo` subclasses will wish to return different names depending on the specific value of `dt` passed, especially if the `tzinfo` class is accounting for daylight time.

The default implementation of `tzname()` raises `NotImplementedError`.

These methods are called by a `datetime` or `time` object, in response to their methods of the same names. A `datetime` object passes itself as the argument, and a `time` object passes `None` as the argument. A `tzinfo` subclass's methods should therefore be prepared to accept a `dt` argument of `None`, or of class `datetime`.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the `tzinfo` protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a `datetime` object is passed in response to a `datetime` method, `dt.tzinfo` is the same object as `self`. `tzinfo` methods can rely on this, unless user code calls `tzinfo` methods directly. The intent is that the `tzinfo` methods interpret `dt` as being in local time, and not need worry about objects in other timezones.

There is one more `tzinfo` method that a subclass may wish to override:

`tzinfo.fromutc(self, dt)`

This is called from the default `datetime.astimezone()` implementation. When called from that, `dt.tzinfo` is `self`, and `dt`'s date and time data are to be viewed as expressing a UTC time. The purpose of `fromutc()` is to adjust the date and time data, returning an equivalent datetime in `self`'s local time.

Most `tzinfo` subclasses should be able to inherit the default `fromutc()` implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default `fromutc()` implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of `astimezone()` and `fromutc()` may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default `fromutc()` implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst # this is self's standard offset
    if delta:
        dt += delta # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

Example `tzinfo` classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)

# A UTC class.

class UTC(tzinfo):
    """UTC"""

    def utcoffset(self, dt):
        return ZERO
```

(continues on next page)

(continued from previous page)

```

    def tzname(self, dt):
        return "UTC"

    def dst(self, dt):
        return ZERO

utc = UTC()

# A class building tzinfo objects for fixed-offset time zones.
# Note that FixedOffset(0, "UTC") is a different way to build a
# UTC tzinfo object.

class FixedOffset(tzinfo):
    """Fixed offset in minutes east from UTC."""

    def __init__(self, offset, name):
        self.__offset = timedelta(minutes = offset)
        self.__name = name

    def utcoffset(self, dt):
        return self.__offset

    def tzname(self, dt):
        return self.__name

    def dst(self, dt):
        return ZERO

# A class capturing the platform's idea of local time.

    elif 1986 < dt.year < 2007:
        dststart, dstend = DSTSTART_1987_2006, DSTEND_1987_2006
    elif 1966 < dt.year < 1987:
        dststart, dstend = DSTSTART_1967_1986, DSTEND_1967_1986
    else:
        return ZERO

    start = first_sunday_on_or_after(dststart.replace(year=dt.year))
    end = first_sunday_on_or_after(dstend.replace(year=dt.year))

    # Can't compare naive to aware objects, so strip the timezone from
    # dt first.
    if start <= dt.replace(tzinfo=None) < end:
        return HOUR
    else:
        return ZERO

Eastern = USTimeZone(-5, "Eastern", "EST", "EDT")
Central = USTimeZone(-6, "Central", "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")

```

Note that there are unavoidable subtleties twice per year in a `tzinfo` subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

| | | | | | | |
|-------|-------|-------|------|------|------|------|
| UTC | 3:MM | 4:MM | 5:MM | 6:MM | 7:MM | 8:MM |
| EST | 22:MM | 23:MM | 0:MM | 1:MM | 2:MM | 3:MM |
| EDT | 23:MM | 0:MM | 1:MM | 2:MM | 3:MM | 4:MM |
| start | 22:MM | 23:MM | 0:MM | 1:MM | 3:MM | 4:MM |
| end | 23:MM | 0:MM | 1:MM | 1:MM | 2:MM | 3:MM |

When DST starts (the “start” line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn’t

really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. In order for `astimezone()` to make this guarantee, the `rzinfo.dst()` method must consider times in the “missing hour” (2:MM for Eastern) to be in daylight time.

When DST ends (the “end” line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. `astimezone()` mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern. In order for `astimezone()` to make this guarantee, the `tzinfo.dst()` method must consider times in the “repeated hour” to be in standard time. This is easily arranged, as in the example, by expressing DST switch times in the time zone's standard local time.

Applications that can't bear such ambiguities should avoid using hybrid `tzinfo` subclasses; there are no ambiguities when using UTC, or any other fixed-offset `tzinfo` subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

See also:

pytz The standard library has no `tzinfo` instances, but there exists a third-party library which brings the *IANA timezone database* (also known as the Olson database) to Python: `pytz`.

`pytz` contains up-to-date information and its usage is recommended.

IANA timezone database The Time Zone Database (often called tz or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

8.1.7 `strftime()` and `strptime()` Behavior

`date`, `datetime`, and `time` objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string. Broadly speaking, `d.strftime(fmt)` acts like the `time` module's `time.strftime(fmt, d.timetuple())` although not all objects support a `timetuple()` method.

Conversely, the `datetime.strptime()` class method creates a `datetime` object from a string representing a date and time and a corresponding format string. `datetime.strptime(date_string, format)` is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`, except when the format includes sub-second components or timezone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

For `time` objects, the format codes for year, month, and day should not be used, as time objects have no such values. If they're used anyway, 1900 is substituted for the year, and 1 for the month and day.

For `date` objects, the format codes for hours, minutes, seconds, and microseconds should not be used, as `date` objects have no such values. If they're used anyway, 0 is substituted for them.

The full set of format codes supported varies across platforms, because Python calls the platform C library's `strftime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation.

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strftime` may raise `UnicodeError` or return an empty string instead.

The following is a list of all the format codes that the C standard (1989 version) requires, and these work on all platforms with a standard C implementation. Note that the 1999 version of the C standard added additional format codes.

The exact range of years for which `strftime()` works also varies across platforms. Regardless of platform, years before 1900 cannot be used.

| Directive | Meaning | Example | Notes |
|------------|---|---|------------------------------|
| %a | Weekday as locale's abbreviated name. | Sun, Mon, ..., Sat (en_US); So, Mo, ..., Sa (de_DE) | (1) |
| %A | Weekday as locale's full name. | Sunday, Monday, ..., Saturday (en_US); Sonntag, Montag, ..., Samstag (de_DE) | (1) |
| %w | Weekday as a decimal number, where 0 is Sunday and 6 is Saturday. | 0, 1, ..., 6 | |
| %d | Day of the month as a zero-padded decimal number. | 01, 02, ..., 31 | |
| %b | Month as locale's abbreviated name. | Jan, Feb, ..., Dec (en_US); Jan, Feb, ..., Dez (de_DE) | (1) |
| %B | Month as locale's full name. | January, February, ..., December (en_US); Januar, Februar, ..., Dezember (de_DE) | (1) |
| %m | Month as a zero-padded decimal number. | 01, 02, ..., 12 | |
| %y | Year without century as a zero-padded decimal number. | 00, 01, ..., 99 | |
| %Y | Year with century as a decimal number. | 1970, 1988, 2001, 2013 | |
| %H | Hour (24-hour clock) as a zero-padded decimal number. | 00, 01, ..., 23 | |
| %I | Hour (12-hour clock) as a zero-padded decimal number. | 01, 02, ..., 12 | |
| %p | Locale's equivalent of either AM or PM. | AM, PM (en_US); am, pm (de_DE) | (1), (2) |
| %M | Minute as a zero-padded decimal number. | 00, 01, ..., 59 | |
| %S | Second as a zero-padded decimal number. | 00, 01, ..., 59 | (3) |
| %f | Microsecond as a decimal number, zero-padded on | 000000, 000001, ..., 999999 | (4) |
| 164 | the left. | | Chapter 8. Data Types |
| %z | UTC offset in the form +HHMM or -HHMM (empty string if the | (empty), +0000, -0400, +1030 | (5) |

Notes:

- (1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, “month/day/year” versus “day/month/year”), and the output may contain Unicode characters encoded using the locale’s default encoding (for example, if the current locale is `ja_JP`, the default encoding could be any one of `eucJP`, `SJIS`, or `utf-8`; use `locale.getlocale()` to determine the current locale’s encoding).
- (2) When used with the `strptime()` method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (3) Unlike the `time` module, the `datetime` module does not support leap seconds.
- (4) `%f` is an extension to the set of format characters in the C standard (but implemented separately in datetime objects, and therefore always available). When used with the `strptime()` method, the `%f` directive accepts from one to six digits and zero pads on the right.

New in version 2.6.

- (5) For a naive object, the `%z` and `%Z` format codes are replaced by empty strings.

For an aware object:

%z `utcoffset()` is transformed into a 5-character string of the form `+HHMM` or `-HHMM`, where `HH` is a 2-digit string giving the number of UTC offset hours, and `MM` is a 2-digit string giving the number of UTC offset minutes. For example, if `utcoffset()` returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

%Z If `tzname()` returns `None`, `%Z` is replaced by an empty string. Otherwise `%Z` is replaced by the returned value, which must be a string.

- (6) When used with the `strptime()` method, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

8.2 calendar — General calendar-related functions

Source code: [Lib/calendar.py](#)

This module allows you to output calendars like the Unix `cal` program, and provides additional useful functions related to the calendar. By default, these calendars have Monday as the first day of the week, and Sunday as the last (the European convention). Use `setfirstweekday()` to set the first day of the week to Sunday (6) or to any other weekday. Parameters that specify dates are given as integers. For related functionality, see also the `datetime` and `time` modules.

Most of these functions and classes rely on the `datetime` module which uses an idealized calendar, the current Gregorian calendar indefinitely extended in both directions. This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book “Calendrical Calculations”, where it’s the base calendar for all computations.

class `calendar.Calendar`(`[firstweekday]`)

Creates a `Calendar` object. `firstweekday` is an integer specifying the first day of the week. 0 is Monday (the default), 6 is Sunday.

A `Calendar` object provides several methods that can be used for preparing the calendar data for formatting. This class doesn’t do any formatting itself. This is the job of subclasses.

New in version 2.5.

`Calendar` instances have the following methods:

iterweekdays ()

Return an iterator for the week day numbers that will be used for one week. The first value from the iterator will be the same as the value of the `firstweekday` property.

itermonthdates (year, month)

Return an iterator for the month *month* (1–12) in the year *year*. This iterator will return all days (as `datetime.date` objects) for the month and all days before the start of the month or after the end of the month that are required to get a complete week.

itermonthdays2 (year, month)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates ()`. Days returned will be tuples consisting of a day number and a week day number.

itermonthdays (year, month)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates ()`. Days returned will simply be day numbers.

monthdatescalendar (year, month)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven `datetime.date` objects.

monthdays2calendar (year, month)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven tuples of day numbers and weekday numbers.

monthdayscalendar (year, month)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven day numbers.

yeardatescalendar (year[, width])

Return the data for the specified year ready for formatting. The return value is a list of month rows. Each month row contains up to *width* months (defaulting to 3). Each month contains between 4 and 6 weeks and each week contains 1–7 days. Days are `datetime.date` objects.

yeardays2calendar (year[, width])

Return the data for the specified year ready for formatting (similar to `yeardatescalendar ()`). Entries in the week lists are tuples of day numbers and weekday numbers. Day numbers outside this month are zero.

yeardayscalendar (year[, width])

Return the data for the specified year ready for formatting (similar to `yeardatescalendar ()`). Entries in the week lists are day numbers. Day numbers outside this month are zero.

class calendar.TextCalendar ([firstweekday])

This class can be used to generate plain text calendars.

New in version 2.5.

`TextCalendar` instances have the following methods:

formatmonth (theyear, themonth[, w[, l]])

Return a month's calendar in a multi-line string. If *w* is provided, it specifies the width of the date columns, which are centered. If *l* is given, it specifies the number of lines that each week will use. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday ()` method.

prmonth (theyear, themonth[, w[, l]])

Print a month's calendar as returned by `formatmonth ()`.

formatyear (theyear[, w[, l[, c[, m]]]])

Return a *m*-column calendar for an entire year as a multi-line string. Optional parameters *w*, *l*, and *c* are for date column width, lines per week, and number of spaces between month columns, respectively. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday ()` method. The earliest year for which a calendar can be generated is platform-dependent.

pryear (*theyear* [, *w* [, *l* [, *c* [, *m*]]]]])

Print the calendar for an entire year as returned by `formatyear()`.

class `calendar.HTMLCalendar` ([*firstweekday*])

This class can be used to generate HTML calendars.

New in version 2.5.

`HTMLCalendar` instances have the following methods:

formatmonth (*theyear*, *themoth* [, *withyear*])

Return a month's calendar as an HTML table. If *withyear* is true the year will be included in the header, otherwise just the month name will be used.

formatyear (*theyear* [, *width*])

Return a year's calendar as an HTML table. *width* (defaulting to 3) specifies the number of months per row.

formatyearpage (*theyear* [, *width* [, *css* [, *encoding*]]]])

Return a year's calendar as a complete HTML page. *width* (defaulting to 3) specifies the number of months per row. *css* is the name for the cascading style sheet to be used. *None* can be passed if no style sheet should be used. *encoding* specifies the encoding to be used for the output (defaulting to the system default encoding).

class `calendar.LocaleTextCalendar` ([*firstweekday* [, *locale*]])

This subclass of `TextCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

New in version 2.5.

class `calendar.LocaleHTMLCalendar` ([*firstweekday* [, *locale*]])

This subclass of `HTMLCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

New in version 2.5.

Note: The `formatweekday()` and `formatmonthname()` methods of these two classes temporarily change the current locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

For simple text calendars this module provides the following functions.

`calendar.setfirstweekday` (*weekday*)

Sets the weekday (0 is Monday, 6 is Sunday) to start each week. The values MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY, SATURDAY, and SUNDAY are provided for convenience. For example, to set the first weekday to Sunday:

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

New in version 2.0.

`calendar.firstweekday` ()

Returns the current setting for the weekday to start each week.

New in version 2.0.

`calendar.isleap` (*year*)

Returns *True* if *year* is a leap year, otherwise *False*.

`calendar.leapdays` (*y1*, *y2*)

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

Changed in version 2.0: This function didn't work for ranges spanning a century change in Python 1.5.2.

`calendar.weekday(year, month, day)`

Returns the day of the week (0 is Monday) for *year* (1970–...), *month* (1–12), *day* (1–31).

`calendar.weekheader(n)`

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

`calendar.monthrange(year, month)`

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

`calendar.monthcalendar(year, month)`

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by `setfirstweekday()`.

`calendar.prmonth(theyear, themonth[, w[, l]])`

Prints a month's calendar as returned by `month()`.

`calendar.month(theyear, themonth[, w[, l]])`

Returns a month's calendar in a multi-line string using the `formatmonth()` of the `TextCalendar` class.

New in version 2.0.

`calendar.prcal(year[, w[, l[c]]])`

Prints the calendar for an entire year as returned by `calendar()`.

`calendar.calendar(year[, w[, l[c]]])`

Returns a 3-column calendar for an entire year as a multi-line string using the `formatyear()` of the `TextCalendar` class.

New in version 2.0.

`calendar.timegm(tuple)`

An unrelated but handy function that takes a time tuple such as returned by the `gmtime()` function in the `time` module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, `time.gmtime()` and `timegm()` are each others' inverse.

New in version 2.0.

The `calendar` module exports the following data attributes:

`calendar.day_name`

An array that represents the days of the week in the current locale.

`calendar.day_abbr`

An array that represents the abbreviated days of the week in the current locale.

`calendar.month_name`

An array that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

`calendar.month_abbr`

An array that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

Module `datetime` Object-oriented interface to dates and times with similar functionality to the `time` module.

Module `time` Low-level time related functions.

8.3 collections — High-performance container datatypes

New in version 2.4.

Source code: `Lib/collections.py` and `Lib/_abcoll.py`

This module implements specialized container datatypes providing alternatives to Python's general purpose built-in containers, *dict*, *list*, *set*, and *tuple*.

| | | |
|---------------------------|--|---------------------|
| <code>namedtuple()</code> | factory function for creating tuple subclasses with named fields | New in version 2.6. |
| <code>deque</code> | list-like container with fast appends and pops on either end | New in version 2.4. |
| <code>Counter</code> | dict subclass for counting hashable objects | New in version 2.7. |
| <code>OrderedDict</code> | dict subclass that remembers the order entries were added | New in version 2.7. |
| <code>defaultdict</code> | dict subclass that calls a factory function to supply missing values | New in version 2.5. |

In addition to the concrete container classes, the collections module provides *abstract base classes* that can be used to test whether a class provides a particular interface, for example, whether it is hashable or a mapping.

8.3.1 Counter objects

A counter tool is provided to support convenient and rapid tallies. For example:

```
>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

class `collections.Counter` (*[iterable-or-mapping]*)

A *Counter* is a *dict* subclass for counting hashable objects. It is an unordered collection where elements are stored as dictionary keys and their counts are stored as dictionary values. Counts are allowed to be any integer value including zero or negative counts. The *Counter* class is similar to bags or multisets in other languages.

Elements are counted from an *iterable* or initialized from another *mapping* (or counter):

```
>>> c = Counter()                                # a new, empty counter
>>> c = Counter('gallahad')                      # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2})            # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)                  # a new counter from keyword args
```

Counter objects have a dictionary interface except that they return a zero count for missing items instead of raising a *KeyError*:

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon']                                     # count of a missing element is zero
0
```

Setting a count to zero does not remove an element from a counter. Use `del` to remove it entirely:

```
>>> c['sausage'] = 0          # counter entry with a zero count
>>> del c['sausage']         # del actually removes the entry
```

New in version 2.7.

Counter objects support three methods beyond those available for all dictionaries:

elements()

Return an iterator over elements repeating each as many times as its count. Elements are returned in arbitrary order. If an element's count is less than one, `elements()` will ignore it.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> list(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

most_common([n])

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or None, `most_common()` returns *all* elements in the counter. Elements with equal counts are ordered arbitrarily:

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('r', 2), ('b', 2)]
```

subtract([iterable-or-mapping])

Elements are subtracted from an *iterable* or from another *mapping* (or counter). Like `dict.update()` but subtracts counts instead of replacing them. Both inputs and outputs may be zero or negative.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

The usual dictionary methods are available for `Counter` objects except for two which work differently for counters.

fromkeys(iterable)

This class method is not implemented for `Counter` objects.

update([iterable-or-mapping])

Elements are counted from an *iterable* or added-in from another *mapping* (or counter). Like `dict.update()` but adds counts instead of replacing them. Also, the *iterable* is expected to be a sequence of elements, not a sequence of (key, value) pairs.

Common patterns for working with `Counter` objects:

```
sum(c.values())          # total of all counts
c.clear()                # reset all counts
list(c)                  # list unique elements
set(c)                   # convert to a set
dict(c)                  # convert to a regular dictionary
c.items()                # convert to a list of (elem, cnt) pairs
Counter(dict(list_of_pairs)) # convert from a list of (elem, cnt) pairs
c.most_common()[:n-1:-1] # n least common elements
c += Counter()           # remove zero and negative counts
```

Several mathematical operations are provided for combining *Counter* objects to produce multisets (counters that have counts greater than zero). Addition and subtraction combine counters by adding or subtracting the counts of corresponding elements. Intersection and union return the minimum and maximum of corresponding counts. Each operation can accept inputs with signed counts, but the output will exclude results with counts of zero or less.

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                                # add two counters together: c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                                # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                                # intersection: min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                                # union: max(c[x], d[x])
Counter({'a': 3, 'b': 2})
```

Note: Counters were primarily designed to work with positive integers to represent running counts; however, care was taken to not unnecessarily preclude use cases needing other types or negative values. To help with those use cases, this section documents the minimum range and type restrictions.

- The *Counter* class itself is a dictionary subclass with no restrictions on its keys and values. The values are intended to be numbers representing counts, but you *could* store anything in the value field.
- The `most_common()` method requires only that the values be orderable.
- For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
- The multiset methods are designed only for use cases with positive values. The inputs may be negative or zero, but only outputs with positive values are created. There are no type restrictions, but the value type needs to support addition, subtraction, and comparison.
- The `elements()` method requires integer counts. It ignores zero and negative counts.

```
map(Counter, combinations_with_replacement('ABC', 2)) -> AA AB AC BB BC CC
```

8.3.2 deque objects

class `collections.deque([iterable[, maxlen]])`

Returns a new deque object initialized left-to-right (using `append()`) with data from *iterable*. If *iterable* is not specified, the new deque is empty.

Dequeues are a generalization of stacks and queues (the name is pronounced “deck” and is short for “double-ended queue”). Deques support thread-safe, memory efficient appends and pops from either side of the deque with approximately the same $O(1)$ performance in either direction.

Though `list` objects support similar operations, they are optimized for fast fixed-length operations and incur $O(n)$ memory movement costs for `pop(0)` and `insert(0, v)` operations which change both the size and position of the underlying data representation.

New in version 2.4.

If *maxlen* is not specified or is `None`, deques may grow to an arbitrary length. Otherwise, the deque is bounded to the specified maximum length. Once a bounded length deque is full, when new items are added, a corresponding number of items are discarded from the opposite end. Bounded length deques provide functionality similar to the `tail` filter in Unix. They are also useful for tracking transactions and other pools of data where only the most recent activity is of interest.

Changed in version 2.6: Added *maxlen* parameter.

Deque objects support the following methods:

append (*x*)

Add *x* to the right side of the deque.

appendleft (*x*)

Add *x* to the left side of the deque.

clear ()

Remove all elements from the deque leaving it with length 0.

count (*x*)

Count the number of deque elements equal to *x*.

New in version 2.7.

extend (*iterable*)

Extend the right side of the deque by appending elements from the *iterable* argument.

extendleft (*iterable*)

Extend the left side of the deque by appending elements from *iterable*. Note, the series of left appends results in reversing the order of elements in the *iterable* argument.

pop ()

Remove and return an element from the right side of the deque. If no elements are present, raises an *IndexError*.

popleft ()

Remove and return an element from the left side of the deque. If no elements are present, raises an *IndexError*.

remove (*value*)

Remove the first occurrence of *value*. If not found, raises a *ValueError*.

New in version 2.5.

reverse ()

Reverse the elements of the deque in-place and then return `None`.

New in version 2.7.

rotate (*n=1*)

Rotate the deque *n* steps to the right. If *n* is negative, rotate to the left.

When the deque is not empty, rotating one step to the right is equivalent to `d.appendleft(d.pop())`, and rotating one step to the left is equivalent to `d.append(d.popleft())`.

Deque objects also provide one read-only attribute:

maxlen

Maximum size of a deque or None if unbounded.

New in version 2.7.

In addition to the above, deques support iteration, pickling, `len(d)`, `reversed(d)`, `copy.copy(d)`, `copy.deepcopy(d)`, membership testing with the `in` operator, and subscript references such as `d[-1]`. Indexed access is $O(1)$ at both ends but slows to $O(n)$ in the middle. For fast random access, use lists instead.

Example:

```
>>> from collections import deque
>>> d = deque('ghi')                # make a new deque with three items
>>> for elem in d:                  # iterate over the deque's elements
...     print elem.upper()
G
H
I

>>> d.append('j')                   # add a new entry to the right side
>>> d.appendleft('f')               # add a new entry to the left side
>>> d                               # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                         # return and remove the rightmost item
'j'
>>> d.popleft()                     # return and remove the leftmost item
'f'
>>> list(d)                         # list the contents of the deque
['g', 'h', 'i']
>>> d[0]                           # peek at leftmost item
'g'
>>> d[-1]                          # peek at rightmost item
'i'

>>> list(reversed(d))              # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d                        # search the deque
True
>>> d.extend('jkl')                # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)                     # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)                   # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))              # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                       # empty the deque
>>> d.pop()                         # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in -toplevel-
    d.pop()
IndexError: pop from an empty deque
```

(continues on next page)

(continued from previous page)

```
>>> d.extendleft('abc')           # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])
```

deque Recipes

This section shows various approaches to working with deques.

Bounded length deques provide functionality similar to the `tail` filter in Unix:

```
def tail(filename, n=10):
    'Return the last n lines of a file'
    return deque(open(filename), n)
```

Another approach to using deques is to maintain a sequence of recently added elements by appending to the right and popping to the left:

```
def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # http://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / float(n)
```

The `rotate()` method provides a way to implement *deque* slicing and deletion. For example, a pure Python implementation of `del d[n]` relies on the `rotate()` method to position elements to be popped:

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

To implement *deque* slicing, use a similar approach applying `rotate()` to bring a target element to the left side of the deque. Remove old entries with `popleft()`, add new entries with `extend()`, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as `dup`, `drop`, `swap`, `over`, `pick`, `rot`, and `roll`.

8.3.3 defaultdict objects

class `collections.defaultdict` (`[default_factory[, ...]]`)

Returns a new dictionary-like object. *defaultdict* is a subclass of the built-in *dict* class. It overrides one method and adds one writable instance variable. The remaining functionality is the same as for the *dict* class and is not documented here.

The first argument provides the initial value for the *default_factory* attribute; it defaults to `None`. All remaining arguments are treated the same as if they were passed to the *dict* constructor, including keyword arguments.

New in version 2.5.

`defaultdict` objects support the following method in addition to the standard `dict` operations:

`__missing__`(*key*)

If the `default_factory` attribute is `None`, this raises a `KeyError` exception with the *key* as argument.

If `default_factory` is not `None`, it is called without arguments to provide a default value for the given *key*, this value is inserted in the dictionary for the *key*, and returned.

If calling `default_factory` raises an exception this exception is propagated unchanged.

This method is called by the `__getitem__()` method of the `dict` class when the requested key is not found; whatever it returns or raises is then returned or raised by `__getitem__()`.

Note that `__missing__()` is *not* called for any operations besides `__getitem__()`. This means that `get()` will, like normal dictionaries, return `None` as a default rather than using `default_factory`.

`defaultdict` objects support the following instance variable:

`default_factory`

This attribute is used by the `__missing__()` method; it is initialized from the first argument to the constructor, if present, or to `None`, if absent.

defaultdict Examples

Using `list` as the `default_factory`, it is easy to group a sequence of key-value pairs into a dictionary of lists:

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> d.items()
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping; so an entry is automatically created using the `default_factory` function which returns an empty list. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally (returning the list for that key) and the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using `dict.setdefault()`:

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> d.items()
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the `default_factory` to `int` makes the `defaultdict` useful for counting (like a bag or multiset in other languages):

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> d.items()
[('i', 4), ('p', 2), ('s', 4), ('m', 1)]
```

When a letter is first encountered, it is missing from the mapping, so the `default_factory` function calls `int()` to supply a default count of zero. The increment operation then builds up the count for each letter.

The function `int()` which always returns zero is just a special case of constant functions. A faster and more flexible way to create constant functions is to use `itertools.repeat()` which can supply any constant value (not just zero):

```
>>> def constant_factory(value):
...     return itertools.repeat(value).next
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the `default_factory` to `set` makes the `defaultdict` useful for building a dictionary of sets:

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> d.items()
[('blue', set([2, 4])), ('red', set([1, 3]))]
```

8.3.4 `namedtuple()` Factory Function for Tuples with Named Fields

Named tuples assign meaning to each position in a tuple and allow for more readable, self-documenting code. They can be used wherever regular tuples are used, and they add the ability to access fields by name instead of position index.

`collections.namedtuple` (`typename`, `field_names` [, `verbose=False`] [, `rename=False`])

Returns a new tuple subclass named `typename`. The new subclass is used to create tuple-like objects that have fields accessible by attribute lookup as well as being indexable and iterable. Instances of the subclass also have a helpful docstring (with `typename` and `field_names`) and a helpful `__repr__()` method which lists the tuple contents in a `name=value` format.

The `field_names` are a sequence of strings such as `['x', 'y']`. Alternatively, `field_names` can be a single string with each fieldname separated by whitespace and/or commas, for example `'x y'` or `'x, y'`.

Any valid Python identifier may be used for a fieldname except for names starting with an underscore. Valid identifiers consist of letters, digits, and underscores but do not start with a digit or underscore and cannot be a `keyword` such as `class`, `for`, `return`, `global`, `pass`, `print`, or `raise`.

If `rename` is true, invalid fieldnames are automatically replaced with positional names. For example, `['abc', 'def', 'ghi', 'abc']` is converted to `['abc', '_1', 'ghi', '_3']`, eliminating the keyword `def` and the duplicate fieldname `abc`.

If `verbose` is true, the class definition is printed just before being built.

Named tuple instances do not have per-instance dictionaries, so they are lightweight and require no more memory than regular tuples.

New in version 2.6.

Changed in version 2.7: added support for `rename`.

Example:

```
>>> Point = namedtuple('Point', ['x', 'y'], verbose=True)
class Point(tuple):
    'Point(x, y)'
```

(continues on next page)

(continued from previous page)

```

__slots__ = ()

_fields = ('x', 'y')

def __new__(_cls, x, y):
    'Create new instance of Point(x, y)'
    return _tuple.__new__(_cls, (x, y))

@classmethod
def _make(cls, iterable, new=tuple.__new__, len=len):
    'Make a new Point object from a sequence or iterable'
    result = new(cls, iterable)
    if len(result) != 2:
        raise TypeError('Expected 2 arguments, got %d' % len(result))
    return result

def __repr__(self):
    'Return a nicely formatted representation string'
    return 'Point(x=%r, y=%r)' % self

def _asdict(self):
    'Return a new OrderedDict which maps field names to their values'
    return OrderedDict(zip(self._fields, self))

def _replace(_self, **kwds):
    'Return a new Point object replacing specified fields with new values'
    result = _self._make(map(kwds.pop, ('x', 'y'), _self))
    if kwds:
        raise ValueError('Got unexpected field names: %r' % kwds.keys())
    return result

def __getnewargs__(self):
    'Return self as a plain tuple.  Used by copy and pickle.'
    return tuple(self)

__dict__ = _property(_asdict)

def __getstate__(self):
    'Exclude the OrderedDict from pickling'
    pass

x = _property(_itemgetter(0), doc='Alias for field number 0')

y = _property(_itemgetter(1), doc='Alias for field number 1')

>>> p = Point(11, y=22)           # instantiate with positional or keyword arguments
>>> p[0] + p[1]                   # indexable like the plain tuple (11, 22)
33
>>> x, y = p                     # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y                    # fields also accessible by name
33
>>> p                           # readable __repr__ with a name=value style

```

(continues on next page)

(continued from previous page)

```
Point(x=11, y=22)
```

Named tuples are especially useful for assigning field names to result tuples returned by the *csv* or *sqlite3* modules:

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade
↪')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print emp.name, emp.title

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print emp.name, emp.title
```

In addition to the methods inherited from tuples, named tuples support three additional methods and one attribute. To prevent conflicts with field names, the method and attribute names start with an underscore.

classmethod *somenamedtuple._make(iterable)*

Class method that makes a new instance from an existing sequence or iterable.

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

somenamedtuple._asdict()

Return a new *OrderedDict* which maps field names to their corresponding values:

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
OrderedDict([('x', 11), ('y', 22)])
```

Changed in version 2.7: Returns an *OrderedDict* instead of a regular *dict*.

*somenamedtuple._replace(**kwargs)*

Return a new instance of the named tuple replacing specified fields with new values:

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum], ↪
↪timestamp=time.now())
```

somenamedtuple._fields

Tuple of strings listing the field names. Useful for introspection and for creating new named tuple types from existing named tuples.

```
>>> p._fields           # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
```

(continues on next page)

(continued from previous page)

```
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

To retrieve a field whose name is stored in a string, use the `getattr()` function:

```
>>> getattr(p, 'x')
11
```

To convert a dictionary to a named tuple, use the double-star-operator (as described in [tut-unpacking-arguments](#)):

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

Since a named tuple is a regular Python class, it is easy to add or change functionality with a subclass. Here is how to add a calculated field and a fixed-width print format:

```
>>> class Point(namedtuple('Point', 'x y')):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f y=%6.3f hypot=%6.3f' % (self.x, self.y, self.
↳hypot)
...
>>> for p in Point(3, 4), Point(14, 5/7.):
...     print p
Point: x= 3.000 y= 4.000 hypot= 5.000
Point: x=14.000 y= 0.714 hypot=14.018
```

The subclass shown above sets `__slots__` to an empty tuple. This helps keep memory requirements low by preventing the creation of instance dictionaries.

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the `_fields` attribute:

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

Default values can be implemented by using `_replace()` to customize a prototype instance:

```
>>> Account = namedtuple('Account', 'owner balance transaction_count')
>>> default_account = Account('<owner name>', 0.0, 0)
>>> johns_account = default_account._replace(owner='John')
```

Enumerated constants can be implemented with named tuples, but it is simpler and more efficient to use a simple class declaration:

```
>>> Status = namedtuple('Status', 'open pending closed')._make(range(3))
>>> Status.open, Status.pending, Status.closed
(0, 1, 2)
>>> class Status:
...     open, pending, closed = range(3)
```

See also:

[Named tuple recipe](#) adapted for Python 2.4.

8.3.5 OrderedDict objects

Ordered dictionaries are just like regular dictionaries but they remember the order that items were inserted. When iterating over an ordered dictionary, the items are returned in the order their keys were first added.

class `collections.OrderedDict` (*[items]*)

Return an instance of a dict subclass, supporting the usual *dict* methods. An *OrderedDict* is a dict that remembers the order that keys were first inserted. If a new entry overwrites an existing entry, the original insertion position is left unchanged. Deleting an entry and reinserting it will move it to the end.

New in version 2.7.

`OrderedDict.popitem` (*last=True*)

The *popitem()* method for ordered dictionaries returns and removes a (key, value) pair. The pairs are returned in LIFO order if *last* is true or FIFO order if false.

In addition to the usual mapping methods, ordered dictionaries also support reverse iteration using *reversed()*.

Equality tests between *OrderedDict* objects are order-sensitive and are implemented as `list(od1.items()) == list(od2.items())`. Equality tests between *OrderedDict* objects and other *Mapping* objects are order-insensitive like regular dictionaries. This allows *OrderedDict* objects to be substituted anywhere a regular dictionary is used.

The *OrderedDict* constructor and *update()* method both accept keyword arguments, but their order is lost because Python's function call semantics pass-in keyword arguments using a regular unordered dictionary.

See also:

Equivalent *OrderedDict* recipe that runs on Python 2.4 or later.

OrderedDict Examples and Recipes

Since an ordered dictionary remembers its insertion order, it can be used in conjunction with sorting to make a sorted dictionary:

```
>>> # regular unsorted dictionary
>>> d = {'banana': 3, 'apple': 4, 'pear': 1, 'orange': 2}

>>> # dictionary sorted by key
>>> OrderedDict(sorted(d.items(), key=lambda t: t[0]))
OrderedDict([('apple', 4), ('banana', 3), ('orange', 2), ('pear', 1)])

>>> # dictionary sorted by value
>>> OrderedDict(sorted(d.items(), key=lambda t: t[1]))
OrderedDict([('pear', 1), ('orange', 2), ('banana', 3), ('apple', 4)])

>>> # dictionary sorted by length of the key string
>>> OrderedDict(sorted(d.items(), key=lambda t: len(t[0])))
OrderedDict([('pear', 1), ('apple', 4), ('orange', 2), ('banana', 3)])
```

The new sorted dictionaries maintain their sort order when entries are deleted. But when new keys are added, the keys are appended to the end and the sort is not maintained.

It is also straight-forward to create an ordered dictionary variant that remembers the order the keys were *last* inserted. If a new entry overwrites an existing entry, the original insertion position is changed and moved to the end:

```
class LastUpdatedOrderedDict (OrderedDict):
    'Store items in the order the keys were last added'
```

(continues on next page)

(continued from previous page)

```
def __setitem__(self, key, value):
    if key in self:
        del self[key]
    OrderedDict.__setitem__(self, key, value)
```

An ordered dictionary can be combined with the *Counter* class so that the counter remembers the order elements are first encountered:

```
class OrderedCounter(Counter, OrderedDict):
    'Counter that remembers the order elements are first encountered'

    def __repr__(self):
        return '%s(%r)' % (self.__class__.__name__, OrderedDict(self))

    def __reduce__(self):
        return self.__class__, (OrderedDict(self),)
```

8.3.6 Collections Abstract Base Classes

The collections module offers the following *ABCs*:

| ABC | Inherits from | Abstract Methods | Mixin Methods |
|--|---|--|--|
| <i>Container</i> | | <code>__contains__</code> | |
| <i>Hashable</i> | | <code>__hash__</code> | |
| <i>Iterable</i> | | <code>__iter__</code> | |
| <i>Iterator</i> | <i>Iterable</i> | <code>next</code> | <code>__iter__</code> |
| <i>Sized</i> | | <code>__len__</code> | |
| <i>Callable</i> | | <code>__call__</code> | |
| <i>Sequence</i> | <i>Sized</i> , <i>Iterable</i> , <i>Container</i> | <code>__getitem__</code> , <code>__len__</code> | <code>__contains__</code> , <code>__iter__</code> , <code>__reversed__</code> , <code>index</code> , and <code>count</code> |
| <i>MutableSequence</i> | <i>Sequence</i> | <code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__len__</code> , <code>insert</code> | Inherited <i>Sequence</i> methods and <code>append</code> , <code>reverse</code> , <code>extend</code> , <code>pop</code> , <code>remove</code> , and <code>__iadd__</code> |
| <i>Set</i> | <i>Sized</i> , <i>Iterable</i> , <i>Container</i> | <code>__contains__</code> , <code>__iter__</code> , <code>__len__</code> | <code>__le__</code> , <code>__lt__</code> , <code>__eq__</code> , <code>__ne__</code> , <code>__gt__</code> , <code>__ge__</code> , <code>__and__</code> , <code>__or__</code> , <code>__sub__</code> , <code>__xor__</code> , and <code>isdisjoint</code> |
| <i>MutableSet</i> | <i>Set</i> | <code>__contains__</code> , <code>__iter__</code> , <code>__len__</code> , <code>add</code> , <code>discard</code> | Inherited <i>Set</i> methods and <code>clear</code> , <code>pop</code> , <code>remove</code> , <code>__ior__</code> , <code>__iand__</code> , <code>__ixor__</code> , and <code>__isub__</code> |
| <i>Mapping</i> | <i>Sized</i> , <i>Iterable</i> , <i>Container</i> | <code>__getitem__</code> , <code>__iter__</code> , <code>__len__</code> | <code>__contains__</code> , <code>keys</code> , <code>items</code> , <code>values</code> , <code>get</code> , <code>__eq__</code> , and <code>__ne__</code> |
| <i>MutableMapping</i> | <i>Mapping</i> | <code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__iter__</code> , <code>__len__</code> | Inherited <i>Mapping</i> methods and <code>pop</code> , <code>popitem</code> , <code>clear</code> , <code>update</code> , and <code>setdefault</code> |
| <i>MappingView</i> | <i>Sized</i> | | <code>__len__</code> |
| <i>ItemsView</i> | <i>MappingView</i> , <i>Set</i> | | <code>__contains__</code> , <code>__iter__</code> |
| <i>KeysView</i> | <i>MappingView</i> , <i>Set</i> | | <code>__contains__</code> , <code>__iter__</code> |
| <i>ValuesView</i> | <i>MappingView</i> | | <code>__contains__</code> , <code>__iter__</code> |

class `collections.Container`

class `collections.Hashable`

class `collections.Sized`

class `collections.Callable`

ABCs for classes that provide respectively the methods `__contains__()`, `__hash__()`, `__len__()`, and `__call__()`.

class `collections.Iterable`

ABC for classes that provide the `__iter__()` method. See also the definition of [*iterable*](#).

class `collections.Iterator`

ABC for classes that provide the `__iter__()` and `next()` methods. See also the definition of [*iterator*](#).

class `collections.Sequence`

class `collections.MutableSequence`

ABCs for read-only and mutable [*sequences*](#).

class `collections.Set`

class `collections.MutableSet`

ABCs for read-only and mutable sets.

```

class collections.Mapping
class collections.MutableMapping
    ABCs for read-only and mutable mappings.

class collections.MappingView
class collections.ItemsView
class collections.KeysView
class collections.ValuesView
    ABCs for mapping, items, keys, and values views.

```

These ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```

size = None
if isinstance(myvar, collections.Sized):
    size = len(myvar)

```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`

```

class ListBasedSet(collections.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2           # The __and__() method is supported automatically

```

Notes on using *Set* and *MutableSet* as a mixin:

- (1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an iterable. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal classmethod called `__from_iterable()` which calls `cls(iterable)` to produce a new set. If the *Set* mixin is being used in a class with a different constructor signature, you will need to override `__from_iterable()` with a classmethod that can construct new instances from an iterable argument.
- (2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.
- (3) The *Set* mixin provides a `__hash__()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are hashable or immutable. To add set hashability using mixins, inherit from both *Set()* and *Hashable()*, then define `__hash__ = Set.__hash__`.

- [OrderedSet](#) recipe for an example built on [MutableSet](#).
- For more about ABCs, see the [abc](#) module and [PEP 3119](#).

8.4 heapq — Heap queue algorithm

New in version 2.3.

Source code: [Lib/heapq.py](#)

This module provides an implementation of the heap queue algorithm, also known as the priority queue algorithm.

Heaps are binary trees for which every parent node has a value less than or equal to any of its children. This implementation uses arrays for which `heap[k] <= heap[2*k+1]` and `heap[k] <= heap[2*k+2]` for all *k*, counting elements from zero. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that its smallest element is always the root, `heap[0]`.

The API below differs from textbook heap algorithms in two aspects: (a) We use zero-based indexing. This makes the relationship between the index for a node and the indexes for its children slightly less obvious, but is more suitable since Python uses zero-based indexing. (b) Our `pop` method returns the smallest item, not the largest (called a “min heap” in textbooks; a “max heap” is more common in texts because of its suitability for in-place sorting).

These two make it possible to view the heap as a regular Python list without surprises: `heap[0]` is the smallest item, and `heap.sort()` maintains the heap invariant!

To create a heap, use a list initialized to `[]`, or you can transform a populated list into a heap via function [heapify\(\)](#).

The following functions are provided:

`heapq.heappush(heap, item)`

Push the value *item* onto the *heap*, maintaining the heap invariant.

`heapq.heappop(heap)`

Pop and return the smallest item from the *heap*, maintaining the heap invariant. If the heap is empty, [IndexError](#) is raised. To access the smallest item without popping it, use `heap[0]`.

`heapq.heappushpop(heap, item)`

Push *item* on the heap, then pop and return the smallest item from the *heap*. The combined action runs more efficiently than [heappush\(\)](#) followed by a separate call to [heappop\(\)](#).

New in version 2.6.

`heapq.heapify(x)`

Transform list *x* into a heap, in-place, in linear time.

`heapq.heapreplace(heap, item)`

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, [IndexError](#) is raised.

This one step operation is more efficient than a [heappop\(\)](#) followed by [heappush\(\)](#) and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using [heappushpop\(\)](#) instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.merge(*iterables)`

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an *iterator* over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

New in version 2.6.

`heapq.nlargest(n, iterable[, key])`

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in the iterable: `key=str.lower`
Equivalent to: `sorted(iterable, key=key, reverse=True)[:n]`

New in version 2.4.

Changed in version 2.5: Added the optional *key* argument.

`heapq.nsmallest(n, iterable[, key])`

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in the iterable: `key=str.lower`
Equivalent to: `sorted(iterable, key=key)[:n]`

New in version 2.4.

Changed in version 2.5: Added the optional *key* argument.

The latter two functions perform best for smaller values of *n*. For larger values, it is more efficient to use the `sorted()` function. Also, when *n*=1, it is more efficient to use the built-in `min()` and `max()` functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

8.4.1 Basic Examples

A *heapsort* can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time:

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike `sorted()`, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked:

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

8.4.2 Priority Queue Implementation Notes

A [priority queue](#) is common use for a heap, and it presents several implementation challenges:

- Sort stability: how do you get two tasks with equal priorities to be returned in the order they were originally added?
- In the future with Python 3, tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap?
- Or if a pending task needs to be deleted, how do you find it and remove it from the queue?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the existing entry as removed and add a new entry with the revised priority:

```
pq = []                                # list of entries arranged in a heap
entry_finder = {}                      # mapping of tasks to entries
REMOVED = '<removed-task>'            # placeholder for a removed task
counter = itertools.count()            # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED. Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')
```

8.4.3 Theory

Heaps are arrays for which $a[k] \leq a[2k+1]$ and $a[k] \leq a[2k+2]$ for all k , counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that $a[0]$ is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are k , not $a[k]$:

In the tree above, each cell k is topping $2*k+1$ and $2*k+2$. In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell “wins” over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the “next” winner is to move some loser (let’s say cell 30 in the diagram above) into the 0 position, and then percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an $O(n \log n)$ sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not “better” than the last 0th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the “win” condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing “runs” (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised¹. It is very important that the initial sort produces the longest runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you’ll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0th item on disk and get an input which may not fit in the current tournament (because the value “wins” over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a ‘heap’ module around. :-)

8.5 bisect — Array bisection algorithm

New in version 2.1.

¹ The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had to be very clever to ensure (far in advance) that each tape movement will be the most effective possible (that is, will best participate at “progressing” the merge). Some tapes were even able to read backwards, and this was also used to avoid the rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

Source code: [Lib/bisect.py](#)

This module provides support for maintaining a list in sorted order without having to sort the list after each insertion. For long lists of items with expensive comparison operations, this can be an improvement over the more common approach. The module is called *bisect* because it uses a basic bisection algorithm to do its work. The source code may be most useful as a working example of the algorithm (the boundary conditions are already right!).

The following functions are provided:

`bisect.bisect_left(a, x, lo=0, hi=len(a))`

Locate the insertion point for *x* in *a* to maintain sorted order. The parameters *lo* and *hi* may be used to specify a subset of the list which should be considered; by default the entire list is used. If *x* is already present in *a*, the insertion point will be before (to the left of) any existing entries. The return value is suitable for use as the first parameter to `list.insert()` assuming that *a* is already sorted.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val < x for val in a[lo:i])` for the left side and `all(val >= x for val in a[i:hi])` for the right side.

`bisect.bisect_right(a, x, lo=0, hi=len(a))`

`bisect.bisect(a, x, lo=0, hi=len(a))`

Similar to `bisect_left()`, but returns an insertion point which comes after (to the right of) any existing entries of *x* in *a*.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val <= x for val in a[lo:i])` for the left side and `all(val > x for val in a[i:hi])` for the right side.

`bisect.insort_left(a, x, lo=0, hi=len(a))`

Insert *x* in *a* in sorted order. This is equivalent to `a.insert(bisect.bisect_left(a, x, lo, hi), x)` assuming that *a* is already sorted. Keep in mind that the $O(\log n)$ search is dominated by the slow $O(n)$ insertion step.

`bisect.insort_right(a, x, lo=0, hi=len(a))`

`bisect.insort(a, x, lo=0, hi=len(a))`

Similar to `insort_left()`, but inserting *x* in *a* after any existing entries of *x*.

See also:

[SortedCollection](#) recipe that uses `bisect` to build a full-featured collection class with straight-forward search methods and support for a key-function. The keys are precomputed to save unnecessary calls to the key function during searches.

8.5.1 Searching Sorted Lists

The above `bisect()` functions are useful for finding insertion points but can be tricky or awkward to use for common searching tasks. The following five functions show how to transform them into the standard lookups for sorted lists:

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
```

(continues on next page)

(continued from previous page)

```

    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

```

8.5.2 Other Examples

The `bisect()` function can be useful for numeric table lookups. This example uses `bisect()` to look up a letter grade for an exam score (say) based on a set of ordered numeric breakpoints: 90 and up is an ‘A’, 80 to 89 is a ‘B’, and so on:

```

>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
    i = bisect(breakpoints, score)
    return grades[i]

>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']

```

Unlike the `sorted()` function, it does not make sense for the `bisect()` functions to have *key* or *reversed* arguments because that would lead to an inefficient design (successive calls to bisect functions would not “remember” all of the previous key lookups).

Instead, it is better to search a list of precomputed keys to find the index of the record in question:

```

>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])
>>> keys = [r[1] for r in data]           # precomputed list of keys
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)

```

8.6 array — Efficient arrays of numeric values

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

| Type code | C Type | Python Type | Minimum size in bytes |
|-----------|----------------|-------------------|-----------------------|
| 'c' | char | character | 1 |
| 'b' | signed char | int | 1 |
| 'B' | unsigned char | int | 1 |
| 'u' | Py_UNICODE | Unicode character | 2 (see note) |
| 'h' | signed short | int | 2 |
| 'H' | unsigned short | int | 2 |
| 'i' | signed int | int | 2 |
| 'I' | unsigned int | long | 2 |
| 'l' | signed long | int | 4 |
| 'L' | unsigned long | long | 4 |
| 'f' | float | float | 4 |
| 'd' | double | float | 8 |

Note: The 'u' typecode corresponds to Python's unicode character. On narrow Unicode builds this is 2-bytes, on wide builds this is 4-bytes.

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the `itemsize` attribute. The values stored for 'L' and 'I' items will be represented as Python long integers when retrieved, because Python's plain integer type cannot represent the full range of C's unsigned (long) integers.

The module defines the following type:

class `array.array`(*typecode*[, *initializer*])

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a list, string, or iterable over elements of the appropriate type.

Changed in version 2.4: Formerly, only lists or strings were accepted.

If given a list or string, the initializer is passed to the new array's `fromlist()`, `fromstring()`, or `fromunicode()` method (see below) to add initial items to the array. Otherwise, the iterable initializer is passed to the `extend()` method.

`array.ArrayType`

Obsolete alias for `array`.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, `TypeError` is raised. Array objects also implement the buffer interface, and may be used wherever buffer objects are supported.

The following data items and methods are also supported:

`array.typecode`

The typecode character used to create the array.

`array.itemsize`

The length in bytes of one array item in the internal representation.

`array.append(x)`

Append a new item with value *x* to the end of the array.

`array.buffer_info()`

Return a tuple (*address*, *length*) giving the current memory address and the length in elements of the buffer used to hold array's contents. The size of the memory buffer in bytes can be computed as `array.buffer_info()[1] * array.itemsize`. This is occasionally useful when working with low-level (and inherently unsafe) I/O interfaces that require memory addresses, such as certain `ioctl()` operations. The returned numbers are valid as long as the array exists and no length-changing operations are applied to it.

Note: When using array objects from code written in C or C++ (the only way to effectively make use of this information), it makes more sense to use the buffer interface supported by array objects. This method is maintained for backward compatibility and should be avoided in new code. The buffer interface is documented in `bufferobjects`.

`array.byteswap()`

“Byteswap” all items of the array. This is only supported for values which are 1, 2, 4, or 8 bytes in size; for other types of values, `RuntimeError` is raised. It is useful when reading data from a file written on a machine with a different byte order.

`array.count(x)`

Return the number of occurrences of *x* in the array.

`array.extend(iterable)`

Append items from *iterable* to the end of the array. If *iterable* is another array, it must have *exactly* the same type code; if not, `TypeError` will be raised. If *iterable* is not an array, it must be iterable and its elements must be the right type to be appended to the array.

Changed in version 2.4: Formerly, the argument could only be another array.

`array.fromfile(f, n)`

Read *n* items (as machine values) from the file object *f* and append them to the end of the array. If less than *n* items are available, `EOFError` is raised, but the items that were available are still inserted into the array. *f* must be a real built-in file object; something else with a `read()` method won't do.

`array.fromlist(list)`

Append items from the list. This is equivalent to `for x in list: a.append(x)` except that if there is a type error, the array is unchanged.

`array.fromstring(s)`

Appends items from the string, interpreting the string as an array of machine values (as if it had been read from a file using the `fromfile()` method).

`array.fromunicode(s)`

Extends this array with data from the given unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised. Use `array.fromstring(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

`array.index(x)`

Return the smallest *i* such that *i* is the index of the first occurrence of *x* in the array.

`array.insert(i, x)`

Insert a new item with value *x* in the array before position *i*. Negative values are treated as being relative to the end of the array.

`array.pop([i])`

Removes the item with the index *i* from the array and returns it. The optional argument defaults to `-1`, so that by default the last item is removed and returned.

`array.read(f, n)`

Deprecated since version 1.5.1: Use the `fromfile()` method.

Read *n* items (as machine values) from the file object *f* and append them to the end of the array. If less than *n* items are available, `EOFError` is raised, but the items that were available are still inserted into the array. *f* must be a real built-in file object; something else with a `read()` method won't do.

`array.remove(x)`

Remove the first occurrence of *x* from the array.

`array.reverse()`

Reverse the order of the items in the array.

`array.tofile(f)`

Write all items (as machine values) to the file object *f*.

`array.tolist()`

Convert the array to an ordinary list with the same items.

`array.tostring()`

Convert the array to an array of machine values and return the string representation (the same sequence of bytes that would be written to a file by the `tofile()` method.)

`array.tounicode()`

Convert the array to a unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised. Use `array.tostring().decode(enc)` to obtain a unicode string from an array of some other type.

`array.write(f)`

Deprecated since version 1.5.1: Use the `tofile()` method.

Write all items (as machine values) to the file object *f*.

When an array object is printed or converted to a string, it is represented as `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a string if the *typecode* is 'c', otherwise it is a list of numbers. The string is guaranteed to be able to be converted back to an array with the same type and value using `eval()`, so long as the `array` class has been imported using `from array import array`. Examples:

```
array('l')
array('c', 'hello world')
array('u', u'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14])
```

The Numerical Python Documentation The Numeric Python extension (NumPy) defines another array type; see <http://www.numpy.org/> for further information about Numerical Python.

8.7 sets — Unordered collections of unique elements

New in version 2.3.

Deprecated since version 2.6: The built-in `set`/`frozenset` types replace this module.

The `sets` module provides classes for constructing and manipulating unordered collections of unique elements. Common uses include membership testing, removing duplicates from a sequence, and computing standard math operations on sets such as intersection, union, difference, and symmetric difference.

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

Most set applications use the `Set` class which provides every set method except for `__hash__()`. For advanced applications requiring a hash method, the `ImmutableSet` class adds a `__hash__()` method but omits methods which alter the contents of the set. Both `Set` and `ImmutableSet` derive from `BaseSet`, an abstract class useful for determining whether something is a set: `isinstance(obj, BaseSet)`.

The set classes are implemented using dictionaries. Accordingly, the requirements for set elements are the same as those for dictionary keys; namely, that the element defines both `__eq__()` and `__hash__()`. As a result, sets cannot contain mutable elements such as lists or dictionaries. However, they can contain immutable collections such as tuples or instances of `ImmutableSet`. For convenience in implementing sets of sets, inner sets are automatically converted to immutable form, for example, `Set([Set(['dog'])])` is transformed to `Set([ImmutableSet(['dog'])])`.

class `sets.Set([iterable])`

Constructs a new empty `Set` object. If the optional `iterable` parameter is supplied, updates the set with elements obtained from iteration. All of the elements in `iterable` should be immutable or be transformable to an immutable using the protocol described in section [Protocol for automatic conversion to immutable](#).

class `sets.ImmutableSet([iterable])`

Constructs a new empty `ImmutableSet` object. If the optional `iterable` parameter is supplied, updates the set with elements obtained from iteration. All of the elements in `iterable` should be immutable or be transformable to an immutable using the protocol described in section [Protocol for automatic conversion to immutable](#).

Because `ImmutableSet` objects provide a `__hash__()` method, they can be used as set elements or as dictionary keys. `ImmutableSet` objects do not have methods for adding or removing elements, so all of the elements must be known when the constructor is called.

8.7.1 Set Objects

Instances of `Set` and `ImmutableSet` both provide the following operations:

| Operation | Equivalent | Result |
|--|------------------------|---|
| <code>len(s)</code> | | number of elements in set <i>s</i> (cardinality) |
| <code>x in s</code> | | test <i>x</i> for membership in <i>s</i> |
| <code>x not in s</code> | | test <i>x</i> for non-membership in <i>s</i> |
| <code>s.issubset(t)</code> | <code>s <= t</code> | test whether every element in <i>s</i> is in <i>t</i> |
| <code>s.issuperset(t)</code> | <code>s >= t</code> | test whether every element in <i>t</i> is in <i>s</i> |
| <code>s.union(t)</code> | <code>s t</code> | new set with elements from both <i>s</i> and <i>t</i> |
| <code>s.intersection(t)</code> | <code>s & t</code> | new set with elements common to <i>s</i> and <i>t</i> |
| <code>s.difference(t)</code> | <code>s - t</code> | new set with elements in <i>s</i> but not in <i>t</i> |
| <code>s.symmetric_difference(t)</code> | <code>s ^ t</code> | new set with elements in either <i>s</i> or <i>t</i> but not both |
| <code>s.copy()</code> | | new set with a shallow copy of <i>s</i> |

Note, the non-operator versions of `union()`, `intersection()`, `difference()`, and `symmetric_difference()` will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `Set('abc') & 'cbs'` in favor of the more readable `Set('abc').intersection('cbs')`.

Changed in version 2.3.1: Formerly all arguments were required to be sets.

In addition, both `Set` and `ImmutableSet` support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

The subset and equality comparisons do not generalize to a complete ordering function. For example, any two disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a < b`, `a == b`, or `a > b`. Accordingly, sets do not implement the `__cmp__()` method.

Since sets only define partial ordering (subset relationships), the output of the `list.sort()` method is undefined for lists of sets.

The following table lists operations available in `ImmutableSet` but not found in `Set`:

| Operation | Result |
|----------------------|---|
| <code>hash(s)</code> | returns a hash value for <code>s</code> |

The following table lists operations available in `Set` but not found in `ImmutableSet`:

| Operation | Equivalent | Result |
|---|-------------------------|--|
| <code>s.update(t)</code> | <code>s = t</code> | return set <code>s</code> with elements added from <code>t</code> |
| <code>s.intersection_update(t)</code> | <code>s &= t</code> | return set <code>s</code> keeping only elements also found in <code>t</code> |
| <code>s.difference_update(t)</code> | <code>s -= t</code> | return set <code>s</code> after removing elements found in <code>t</code> |
| <code>s.symmetric_difference_update(t)</code> | <code>s ^= t</code> | return set <code>s</code> with elements from <code>s</code> or <code>t</code> but not both |
| <code>s.add(x)</code> | | add element <code>x</code> to set <code>s</code> |
| <code>s.remove(x)</code> | | remove <code>x</code> from set <code>s</code> ; raises <code>KeyError</code> if not present |
| <code>s.discard(x)</code> | | removes <code>x</code> from set <code>s</code> if present |
| <code>s.pop()</code> | | remove and return an arbitrary element from <code>s</code> ; raises <code>KeyError</code> if empty |
| <code>s.clear()</code> | | remove all elements from set <code>s</code> |

Note, the non-operator versions of `update()`, `intersection_update()`, `difference_update()`, and `symmetric_difference_update()` will accept any iterable as an argument.

Changed in version 2.3.1: Formerly all arguments were required to be sets.

Also note, the module also includes a `union_update()` method which is an alias for `update()`. The method is included for backwards compatibility. Programmers should prefer the `update()` method because it is supported by the built-in `set()` and `frozenset()` types.

8.7.2 Example

```
>>> from sets import Set
>>> engineers = Set(['John', 'Jane', 'Jack', 'Janice'])
>>> programmers = Set(['Jack', 'Sam', 'Susan', 'Janice'])
>>> managers = Set(['Jane', 'Jack', 'Susan', 'Zack'])
>>> employees = engineers | programmers | managers           # union
>>> engineering_management = engineers & managers           # intersection
>>> fulltime_management = managers - engineers - programmers # difference
>>> engineers.add('Marvin')                                   # add element
>>> print engineers # doctest: +SKIP
Set(['Jane', 'Marvin', 'Janice', 'John', 'Jack'])
>>> employees.issuperset(engineers)                          # superset test
```

(continues on next page)

(continued from previous page)

```

False
>>> employees.update(engineers)           # update from another set
>>> employees.issuperset(engineers)
True
>>> for group in [engineers, programmers, managers, employees]: # doctest: +SKIP
...     group.discard('Susan')           # unconditionally remove element
...     print group
...
Set(['Jane', 'Marvin', 'Janice', 'John', 'Jack'])
Set(['Janice', 'Jack', 'Sam'])
Set(['Jane', 'Zack', 'Jack'])
Set(['Jack', 'Sam', 'Jane', 'Marvin', 'Janice', 'John', 'Zack'])

```

8.7.3 Protocol for automatic conversion to immutable

Sets can only contain immutable elements. For convenience, mutable *Set* objects are automatically copied to an *ImmutableSet* before being added as a set element.

The mechanism is to always add a *hashable* element, or if it is not hashable, the element is checked to see if it has an `__as_immutable__()` method which returns an immutable equivalent.

Since *Set* objects have a `__as_immutable__()` method returning an instance of *ImmutableSet*, it is possible to construct sets of sets.

A similar mechanism is needed by the `__contains__()` and `remove()` methods which need to hash an element to check for membership in a set. Those methods check an element for hashability and, if not, check for a `__as_temporarily_immutable__()` method which returns the element wrapped by a class that provides temporary methods for `__hash__()`, `__eq__()`, and `__ne__()`.

The alternate mechanism spares the need to build a separate copy of the original mutable object.

Set objects implement the `__as_temporarily_immutable__()` method which returns the *Set* object wrapped by a new class *_TemporarilyImmutableSet*.

The two mechanisms for adding hashability are normally invisible to the user; however, a conflict can arise in a multi-threaded environment where one thread is updating a set while another has temporarily wrapped it in *_TemporarilyImmutableSet*. In other words, sets of mutable sets are not thread-safe.

8.7.4 Comparison to the built-in set types

The built-in *set* and *frozenset* types were designed based on lessons learned from the *sets* module. The key differences are:

- *Set* and *ImmutableSet* were renamed to *set* and *frozenset*.
- There is no equivalent to *BaseSet*. Instead, use `isinstance(x, (set, frozenset))`.
- The hash algorithm for the built-ins performs significantly better (fewer collisions) for most datasets.
- The built-in versions have more space efficient pickles.
- The built-in versions do not have a `union_update()` method. Instead, use the `update()` method which is equivalent.
- The built-in versions do not have a `__repr(sorted=True)` method. Instead, use the built-in `repr()` and `sorted()` functions: `repr(sorted(s))`.

- The built-in version does not have a protocol for automatic conversion to immutable. Many found this feature to be confusing and no one in the community reported having found real uses for it.

8.8 sched — Event scheduler

Source code: [Lib/sched.py](#)

The `sched` module defines a class which implements a general purpose event scheduler:

class `sched.scheduler` (*timefunc*, *delayfunc*)

The `scheduler` class defines a generic interface to scheduling events. It needs two functions to actually deal with the “outside world” — *timefunc* should be callable without arguments, and return a number (the “time”, in any units whatsoever). The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

Example:

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(): print "From print_time", time.time()
...
>>> def print_some_times():
...     print time.time()
...     s.enter(5, 1, print_time, ())
...     s.enter(10, 1, print_time, ())
...     s.run()
...     print time.time()
...
>>> print_some_times()
930343690.257
From print_time 930343695.274
From print_time 930343700.273
930343700.276
```

In multi-threaded environments, the `scheduler` class has limitations with respect to thread-safety, inability to insert a new task before the one currently pending in a running scheduler, and holding up the main thread until the event queue is empty. Instead, the preferred approach is to use the `threading.Timer` class instead.

Example:

```
>>> import time
>>> from threading import Timer
>>> def print_time():
...     print "From print_time", time.time()
...
>>> def print_some_times():
...     print time.time()
...     Timer(5, print_time, ()).start()
...     Timer(10, print_time, ()).start()
...     time.sleep(11) # sleep while time-delay events execute
...     print time.time()
...
>>> print_some_times()
930343690.257
```

(continues on next page)

(continued from previous page)

```

From print_time 930343695.274
From print_time 930343700.273
930343701.301

```

8.8.1 Scheduler Objects

`scheduler` instances have the following methods and attributes:

`scheduler.enterabs` (*time*, *priority*, *action*, *argument*)

Schedule a new event. The *time* argument should be a numeric type compatible with the return value of the *timefunc* function passed to the constructor. Events scheduled for the same *time* will be executed in the order of their *priority*. A lower number represents a higher priority.

Executing the event means executing `action(*argument)`. *argument* must be a sequence holding the parameters for *action*.

Return value is an event which may be used for later cancellation of the event (see `cancel()`).

`scheduler.enter` (*delay*, *priority*, *action*, *argument*)

Schedule an event for *delay* more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for `enterabs()`.

`scheduler.cancel` (*event*)

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a `ValueError`.

`scheduler.empty` ()

Return true if the event queue is empty.

`scheduler.run` ()

Run all scheduled events. This function will wait (using the `delayfunc()` function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to `run()`.

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

`scheduler.queue`

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a *named tuple* with the following fields: time, priority, action, argument.

New in version 2.6.

8.9 mutex — Mutual exclusion support

Deprecated since version 2.6: The `mutex` module has been removed in Python 3.

The `mutex` module defines a class that allows mutual-exclusion via acquiring and releasing locks. It does not require (or imply) `threading` or multi-tasking, though it could be useful for those purposes.

The `mutex` module defines the following class:

class `mutex.mutex`

Create a new (unlocked) mutex.

A mutex has two pieces of state — a “locked” bit and a queue. When the mutex is not locked, the queue is empty. Otherwise, the queue contains zero or more (`function`, `argument`) pairs representing functions (or methods) waiting to acquire the lock. When the mutex is unlocked while the queue is not empty, the first queue entry is removed and its `function(argument)` pair called, implying it now has the lock.

Of course, no multi-threading is implied – hence the funny interface for `lock()`, where a function is called once the lock is acquired.

8.9.1 Mutex Objects

`mutex` objects have following methods:

`mutex.test()`

Check whether the mutex is locked.

`mutex.testandset()`

“Atomic” test-and-set, grab the lock if it is not set, and return `True`, otherwise, return `False`.

`mutex.lock(function, argument)`

Execute `function(argument)`, unless the mutex is locked. In the case it is locked, place the function and argument on the queue. See `unlock()` for explanation of when `function(argument)` is executed in that case.

`mutex.unlock()`

Unlock the mutex if queue is empty, otherwise execute the first element in the queue.

8.10 Queue — A synchronized queue class

Note: The `Queue` module has been renamed to `queue` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

Source code: [Lib/Queue.py](#)

The `Queue` module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The `Queue` class in this module implements all the required locking semantics. It depends on the availability of thread support in Python; see the `threading` module.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the `heapq` module) and the lowest valued entry is retrieved first.

The `Queue` module defines the following classes and exceptions:

class `Queue.Queue(maxsize=0)`

Constructor for a FIFO queue. `maxsize` is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If `maxsize` is less than or equal to zero, the queue size is infinite.

class `Queue.LifoQueue (maxsize=0)`

Constructor for a LIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

New in version 2.6.

class `Queue.PriorityQueue (maxsize=0)`

Constructor for a priority queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one returned by `sorted(list(entries))[0]`). A typical pattern for entries is a tuple in the form: `(priority_number, data)`.

New in version 2.6.

exception `Queue.Empty`

Exception raised when non-blocking `get()` (or `get_nowait()`) is called on a `Queue` object which is empty.

exception `Queue.Full`

Exception raised when non-blocking `put()` (or `put_nowait()`) is called on a `Queue` object which is full.

See also:

`collections.deque` is an alternative implementation of unbounded queues with fast atomic `append()` and `popleft()` operations that do not require locking.

8.10.1 Queue Objects

Queue objects (`Queue`, `LifoQueue`, or `PriorityQueue`) provide the public methods described below.

`Queue.qsize()`

Return the approximate size of the queue. Note, `qsize() > 0` doesn't guarantee that a subsequent `get()` will not block, nor will `qsize() < maxsize` guarantee that `put()` will not block.

`Queue.empty()`

Return `True` if the queue is empty, `False` otherwise. If `empty()` returns `True` it doesn't guarantee that a subsequent call to `put()` will not block. Similarly, if `empty()` returns `False` it doesn't guarantee that a subsequent call to `get()` will not block.

`Queue.full()`

Return `True` if the queue is full, `False` otherwise. If `full()` returns `True` it doesn't guarantee that a subsequent call to `get()` will not block. Similarly, if `full()` returns `False` it doesn't guarantee that a subsequent call to `put()` will not block.

`Queue.put (item[, block[, timeout]])`

Put *item* into the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the `Full` exception if no free slot was available within that time. Otherwise (*block* is false), put an item on the queue if a free slot is immediately available, else raise the `Full` exception (*timeout* is ignored in that case).

New in version 2.3: The *timeout* parameter.

`Queue.put_nowait (item)`

Equivalent to `put(item, False)`.

`Queue.get ([block[, timeout]])`

Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block

if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Empty* exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the *Empty* exception (*timeout* is ignored in that case).

New in version 2.3: The *timeout* parameter.

`Queue.get_nowait()`

Equivalent to `get(False)`.

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

`Queue.task_done()`

Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises a *ValueError* if called more times than there were items placed in the queue.

New in version 2.5.

`Queue.join()`

Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

New in version 2.5.

Example of how to wait for enqueued tasks to be completed:

```
def worker():
    while True:
        item = q.get()
        do_work(item)
        q.task_done()

q = Queue()
for i in range(num_worker_threads):
    t = Thread(target=worker)
    t.daemon = True
    t.start()

for item in source():
    q.put(item)

q.join()           # block until all tasks are done
```

8.11 weakref — Weak references

New in version 2.1.

Source code: [Lib/weakref.py](#)

The *weakref* module allows the Python programmer to create *weak references* to objects.

In the following, the term *referent* means the object which is referred to by a weak reference.

A weak reference to an object is not enough to keep the object alive: when the only remaining references to a referent are weak references, *garbage collection* is free to destroy the referent and reuse its memory for something else. A primary use for weak references is to implement caches or mappings holding large objects, where it's desired that a large object not be kept alive solely because it appears in a cache or mapping.

For example, if you have a number of large binary image objects, you may wish to associate a name with each. If you used a Python dictionary to map names to images, or images to names, the image objects would remain alive just because they appeared as values or keys in the dictionaries. The *WeakKeyDictionary* and *WeakValueDictionary* classes supplied by the *weakref* module are an alternative, using weak references to construct mappings that don't keep objects alive solely because they appear in the mapping objects. If, for example, an image object is a value in a *WeakValueDictionary*, then when the last remaining references to that image object are the weak references held by weak mappings, garbage collection can reclaim the object, and its corresponding entries in weak mappings are simply deleted.

WeakKeyDictionary and *WeakValueDictionary* use weak references in their implementation, setting up callback functions on the weak references that notify the weak dictionaries when a key or value has been reclaimed by garbage collection. Most programs should find that using one of these weak dictionary types is all they need – it's not usually necessary to create your own weak references directly. The low-level machinery used by the weak dictionary implementations is exposed by the *weakref* module for the benefit of advanced uses.

Not all objects can be weakly referenced; those objects which can include class instances, functions written in Python (but not in C), methods (both bound and unbound), sets, frozensets, file objects, *generators*, type objects, *DBcursor* objects from the *bsddb* module, sockets, arrays, dequeues, regular expression pattern objects, and code objects.

Changed in version 2.4: Added support for files, sockets, arrays, and patterns.

Changed in version 2.7: Added support for *thread.lock*, *threading.Lock*, and code objects.

Several built-in types such as *list* and *dict* do not directly support weak references but can add support through subclassing:

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)  # this object is weak referenceable
```

CPython implementation detail: Other built-in types such as *tuple* and *long* do not support weak references even when subclassed.

Extension types can easily be made to support weak references; see *weakref-support*.

class *weakref.ref*(*object*[, *callback*])

Return a weak reference to *object*. The original object can be retrieved by calling the reference object if the referent is still alive; if the referent is no longer alive, calling the reference object will cause *None* to be returned. If *callback* is provided and not *None*, and the returned *weakref* object is still alive, the callback will be called when the object is about to be finalized; the weak reference object will be passed as the only parameter to the callback; the referent will no longer be available.

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated; they are handled in exactly the same way as exceptions raised from an object's *__del__*() method.

Weak references are *hashable* if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If *hash()* is called the first time only after the *object* was deleted, the call will raise *TypeError*.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the

references are equal only if the reference objects are the same object.

Changed in version 2.4: This is now a subclassable type rather than a factory function; it derives from *object*.

`weakref.proxy(object[, callback])`

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either `ProxyType` or `CallableProxyType`, depending on whether *object* is callable. Proxy objects are not *hashable* regardless of the referent; this avoids a number of problems related to their fundamentally mutable nature, and prevent their use as dictionary keys. *callback* is the same as the parameter of the same name to the `ref()` function.

`weakref.getweakrefcount(object)`

Return the number of weak references and proxies which refer to *object*.

`weakref.getweakrefs(object)`

Return a list of all weak reference and proxy objects which refer to *object*.

class `weakref.WeakKeyDictionary([dict])`

Mapping class that references keys weakly. Entries in the dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

Note: Caution: Because a *WeakKeyDictionary* is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a *WeakKeyDictionary* because actions performed by the program during iteration may cause items in the dictionary to vanish “by magic” (as a side effect of garbage collection).

WeakKeyDictionary objects have the following additional methods. These expose the internal references directly. The references are not guaranteed to be “live” at the time they are used, so the result of calling the references needs to be checked before being used. This can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

`WeakKeyDictionary.iterkeyrefs()`

Return an iterable of the weak references to the keys.

New in version 2.5.

`WeakKeyDictionary.keyrefs()`

Return a list of weak references to the keys.

New in version 2.5.

class `weakref.WeakValueDictionary([dict])`

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

Note: Caution: Because a *WeakValueDictionary* is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a *WeakValueDictionary* because actions performed by the program during iteration may cause items in the dictionary to vanish “by magic” (as a side effect of garbage collection).

WeakValueDictionary objects have the following additional methods. These methods have the same issues as the `iterkeyrefs()` and `keyrefs()` methods of *WeakKeyDictionary* objects.

`WeakValueDictionary.itervaluerefs()`
 Return an iterable of the weak references to the values.
 New in version 2.5.

`WeakValueDictionary.valuerefs()`
 Return a list of weak references to the values.
 New in version 2.5.

class `weakref.WeakSet([elements])`
 Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.
 New in version 2.7.

`weakref.ReferenceType`
 The type object for weak references objects.

`weakref.ProxyType`
 The type object for proxies of objects which are not callable.

`weakref.CallableProxyType`
 The type object for proxies of callable objects.

`weakref.ProxyTypes`
 Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

exception `weakref.ReferenceError`
 Exception raised when a proxy object is used but the underlying object has been collected. This is the same as the standard [ReferenceError](#) exception.

See also:

PEP 205 - Weak References The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

8.11.1 Weak Reference Objects

Weak reference objects have no attributes or methods, but do allow the referent to be obtained, if it still exists, by calling it:

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns [None](#):

```
>>> del o, o2
>>> print r()
None
```

Testing that a weak reference object is still live should be done using the expression `ref() is not None`. Normally, application code that needs to use a reference object should follow this pattern:

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print "Object has been deallocated; can't frobnicate."
else:
    print "Object is still live!"
    o.do_something_useful()
```

Using a separate test for “liveness” creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of `ref` objects can be created through subclassing. This is used in the implementation of the `WeakValueDictionary` to reduce the memory overhead for each entry in the mapping. This may be most useful to associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of `ref` can be used to store additional information about an object and affect the value that’s returned when the referent is accessed:

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, **annotations):
        super(ExtendedRef, self).__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.iteritems():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super(ExtendedRef, self).__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

8.11.2 Example

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
```

(continues on next page)

(continued from previous page)

```

    return oid

def id2obj(oid):
    return _id2obj_dict[oid]

```

8.12 UserDict — Class wrapper for dictionary objects

Source code: [Lib/UserDict.py](#)

The module defines a mixin, *DictMixin*, defining all dictionary methods for classes that already have a minimum mapping interface. This greatly simplifies writing classes that need to be substitutable for dictionaries (such as the *shelve* module).

This module also defines a class, *UserDict*, that acts as a wrapper around dictionary objects. The need for this class has been largely supplanted by the ability to subclass directly from *dict* (a feature that became available starting with Python version 2.2). Prior to the introduction of *dict*, the *UserDict* class was used to create dictionary-like sub-classes that obtained new behaviors by overriding existing methods or adding new ones.

The *UserDict* module defines the *UserDict* class and *DictMixin*:

class *UserDict.UserDict* (*initialdata*)

Class that simulates a dictionary. The instance's contents are kept in a regular dictionary, which is accessible via the *data* attribute of *UserDict* instances. If *initialdata* is provided, *data* is initialized with its contents; note that a reference to *initialdata* will not be kept, allowing it be used for other purposes.

Note: For backward compatibility, instances of *UserDict* are not iterable.

class *UserDict.IterableUserDict* (*initialdata*)

Subclass of *UserDict* that supports direct iteration (e.g. `for key in myDict`).

In addition to supporting the methods and operations of mappings (see section *Mapping Types — dict*), *UserDict* and *IterableUserDict* instances provide the following attribute:

IterableUserDict.data

A real dictionary used to store the contents of the *UserDict* class.

class *UserDict.DictMixin*

Mixin defining all dictionary methods for classes that already have a minimum dictionary interface including `__getitem__()`, `__setitem__()`, `__delitem__()`, and `keys()`.

This mixin should be used as a superclass. Adding each of the above methods adds progressively more functionality. For instance, defining all but `__delitem__()` will preclude only `pop()` and `popitem()` from the full interface.

In addition to the four base methods, progressively more efficiency comes with defining `__contains__()`, `__iter__()`, and `iteritems()`.

Since the mixin has no knowledge of the subclass constructor, it does not define `__init__()` or `copy()`.

Starting with Python version 2.6, it is recommended to use *collections.MutableMapping* instead of *DictMixin*.

Note that *DictMixin* does not implement the *viewkeys()*, *viewvalues()*, or *viewitems()* methods.

8.13 `UserList` — Class wrapper for list objects

Note: When Python 2.2 was released, many of the use cases for this class were subsumed by the ability to subclass `list` directly. However, a handful of use cases remain.

This module provides a list-interface around an underlying data store. By default, that data store is a `list`; however, it can be used to wrap a list-like interface around other objects (such as persistent storage).

In addition, this class can be mixed-in with built-in classes using multiple inheritance. This can sometimes be useful. For example, you can inherit from `UserList` and `str` at the same time. That would not be possible with both a real `list` and a real `str`.

This module defines a class that acts as a wrapper around list objects. It is a useful base class for your own list-like classes, which can inherit from them and override existing methods or add new ones. In this way one can add new behaviors to lists.

The `UserList` module defines the `UserList` class:

```
class UserList.UserList ([list])
```

Class that simulates a list. The instance's contents are kept in a regular list, which is accessible via the `data` attribute of `UserList` instances. The instance's contents are initially set to a copy of *list*, defaulting to the empty list `[]`. *list* can be any iterable, e.g. a real Python list or a `UserList` object.

Note: The `UserList` class has been moved to the `collections` module in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

In addition to supporting the methods and operations of mutable sequences (see section *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*), `UserList` instances provide the following attribute:

`UserList.data`

A real Python list object used to store the contents of the `UserList` class.

Subclassing requirements: Subclasses of `UserList` are expected to offer a constructor which can be called with either no arguments or one argument. List operations which return a new sequence attempt to create an instance of the actual implementation class. To do so, it assumes that the constructor can be called with a single parameter, which is a sequence object used as a data source.

If a derived class does not wish to comply with this requirement, all of the special methods supported by this class will need to be overridden; please consult the sources for information about the methods which need to be provided in that case.

Changed in version 2.0: Python versions 1.5.2 and 1.6 also required that the constructor be callable with no parameters, and offer a mutable `data` attribute. Earlier versions of Python did not attempt to create instances of the derived class.

8.14 `UserString` — Class wrapper for string objects

Note: This `UserString` class from this module is available for backward compatibility only. If you are writing code that does not need to work with versions of Python earlier than Python 2.2, please consider subclassing directly from the built-in `str` type instead of using `UserString` (there is no built-in equivalent to `MutableString`).

This module defines a class that acts as a wrapper around string objects. It is a useful base class for your own string-like classes, which can inherit from them and override existing methods or add new ones. In this way one can add new behaviors to strings.

It should be noted that these classes are highly inefficient compared to real string or Unicode objects; this is especially the case for *MutableString*.

The *UserString* module defines the following classes:

class *UserString.UserString*([*sequence*])

Class that simulates a string or a Unicode string object. The instance's content is kept in a regular string or Unicode string object, which is accessible via the *data* attribute of *UserString* instances. The instance's contents are initially set to a copy of *sequence*. *sequence* can be either a regular Python string or Unicode string, an instance of *UserString* (or a subclass) or an arbitrary sequence which can be converted into a string using the built-in *str()* function.

Note: The *UserString* class has been moved to the *collections* module in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

class *UserString.MutableString*([*sequence*])

This class is derived from the *UserString* above and redefines strings to be *mutable*. Mutable strings can't be used as dictionary keys, because dictionaries require *immutable* objects as keys. The main intention of this class is to serve as an educational example for inheritance and necessity to remove (override) the *__hash__()* method in order to trap attempts to use a mutable object as dictionary key, which would be otherwise very error prone and hard to track down.

Deprecated since version 2.6: The *MutableString* class has been removed in Python 3.

In addition to supporting the methods and operations of string and Unicode objects (see section *String Methods*), *UserString* instances provide the following attribute:

MutableString.data

A real Python string or Unicode object used to store the content of the *UserString* class.

8.15 types — Names for built-in types

Source code: *Lib/types.py*

This module defines names for some object types that are used by the standard Python interpreter, but not for the types defined by various extension modules. Also, it does not include some of the types that arise during processing such as the *listiterator* type. It is safe to use *from types import ** — the module does not export any names besides the ones listed here. New names exported by future versions of this module will all end in *Type*.

Typical use is for functions that do different things depending on their argument types, like the following:

```
from types import *
def delete(mylist, item):
    if type(item) is IntType:
        del mylist[item]
    else:
        mylist.remove(item)
```

Starting in Python 2.2, built-in factory functions such as *int()* and *str()* are also names for the corresponding types. This is now the preferred way to access the type instead of using the *types* module. Accordingly, the example above should be written as follows:

```
def delete(mylist, item):
    if isinstance(item, int):
        del mylist[item]
    else:
        mylist.remove(item)
```

The module defines the following names:

types.NoneType

The type of `None`.

types.TypeType

The type of type objects (such as returned by `type()`); alias of the built-in `type`.

types.BooleanType

The type of the `bool` values `True` and `False`; alias of the built-in `bool`.

New in version 2.3.

types.IntType

The type of integers (e.g. `1`); alias of the built-in `int`.

types.LongType

The type of long integers (e.g. `1L`); alias of the built-in `long`.

types.FloatType

The type of floating point numbers (e.g. `1.0`); alias of the built-in `float`.

types.ComplexType

The type of complex numbers (e.g. `1.0j`). This is not defined if Python was built without complex number support.

types.StringType

The type of character strings (e.g. `'Spam'`); alias of the built-in `str`.

types.UnicodeType

The type of Unicode character strings (e.g. `u'Spam'`). This is not defined if Python was built without Unicode support. It's an alias of the built-in `unicode`.

types.TupleType

The type of tuples (e.g. `(1, 2, 3, 'Spam')`); alias of the built-in `tuple`.

types.ListType

The type of lists (e.g. `[0, 1, 2, 3]`); alias of the built-in `list`.

types.DictType

The type of dictionaries (e.g. `{'Bacon': 1, 'Ham': 0}`); alias of the built-in `dict`.

types.DictionaryType

An alternate name for `DictType`.

types.FunctionType

types.LambdaType

The type of user-defined functions and functions created by `lambda` expressions.

types.GeneratorType

The type of *generator*-iterator objects, produced by calling a generator function.

New in version 2.2.

types.CodeType

The type for code objects such as returned by `compile()`.

types.ClassType

The type of user-defined old-style classes.

types.InstanceType

The type of instances of user-defined old-style classes.

types.MethodType

The type of methods of user-defined class instances.

types.UnboundMethodType

An alternate name for `MethodType`.

types.BuiltinFunctionType**types.BuiltinMethodType**

The type of built-in functions like `len()` or `sys.exit()`, and methods of built-in classes. (Here, the term “built-in” means “written in C”.)

types.ModuleType

The type of modules.

types.FileType

The type of open file objects such as `sys.stdout`; alias of the built-in `file`.

types.XRangeType

The type of range objects returned by `xrange()`; alias of the built-in `xrange`.

types.SliceType

The type of objects returned by `slice()`; alias of the built-in `slice`.

types.EllipsisType

The type of `Ellipsis`.

types.TracebackType

The type of traceback objects such as found in `sys.exc_traceback`.

types.FrameType

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

types.BufferType

The type of buffer objects created by the `buffer()` function.

types.DictProxyType

The type of dict proxies, such as `TypeType.__dict__`.

types.NotImplementedType

The type of `NotImplemented`

types.GetSetDescriptorType

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the `property` type, but for classes defined in extension modules.

New in version 2.5.

types.MemberDescriptorType

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the `property` type, but for classes defined in extension modules.

CPython implementation detail: In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

New in version 2.5.

types.StringTypes

A sequence containing `StringType` and `UnicodeType` used to facilitate easier checking for any string object. Using this is more portable than using a sequence of the two string types constructed elsewhere since it only contains `UnicodeType` if it has been built in the running version of Python. For example: `instance(s, types.StringTypes)`.

New in version 2.2.

8.16 new — Creation of runtime internal objects

Deprecated since version 2.6: The `new` module has been removed in Python 3. Use the `types` module's classes instead.

The `new` module allows an interface to the interpreter object creation functions. This is for use primarily in marshal-type functions, when a new object needs to be created “magically” and not by using the regular creation functions. This module provides a low-level interface to the interpreter, so care must be exercised when using this module. It is possible to supply non-sensical arguments which crash the interpreter when the object is used.

The `new` module defines the following functions:

`new.instance(class[, dict])`

This function creates an instance of `class` with dictionary `dict` without calling the `__init__()` constructor. If `dict` is omitted or `None`, a new, empty dictionary is created for the new instance. Note that there are no guarantees that the object will be in a consistent state.

`new.instancemethod(function, instance, class)`

This function will return a method object, bound to `instance`, or unbound if `instance` is `None`. `function` must be callable.

`new.function(code, globals[, name[, argdefs[, closure]]])`

Returns a (Python) function with the given code and globals. If `name` is given, it must be a string or `None`. If it is a string, the function will have the given name, otherwise the function name will be taken from `code.co_name`. If `argdefs` is given, it must be a tuple and will be used to determine the default values of parameters. If `closure` is given, it must be `None` or a tuple of cell objects containing objects to bind to the names in `code.co_freevars`.

`new.code(argcount, nlocals, stacksize, flags, codestring, constants, names, varnames, filename, name, firstlineno, lnotab)`

This function is an interface to the `PyCode_New()` C function.

`new.module(name[, doc])`

This function returns a new module object with name `name`. `name` must be a string. The optional `doc` argument can have any type.

`new.classobj(name, baseclasses, dict)`

This function returns a new class object, with name `name`, derived from `baseclasses` (which should be a tuple of classes) and with namespace `dict`.

8.17 copy — Shallow and deep copy operations

Assignment statements in Python do not copy objects, they create bindings between a target and an object. For collections that are mutable or contain mutable items, a copy is sometimes needed so one can change one copy without changing the other. This module provides generic shallow and deep copy operations (explained below).

Interface summary:

`copy.copy(x)`

Return a shallow copy of `x`.

`copy.deepcopy(x)`

Return a deep copy of *x*.

exception `copy.error`

Raised for module specific errors.

The difference between shallow and deep copying is only relevant for compound objects (objects that contain other objects, like lists or class instances):

- A *shallow copy* constructs a new compound object and then (to the extent possible) inserts *references* into it to the objects found in the original.
- A *deep copy* constructs a new compound object and then, recursively, inserts *copies* into it of the objects found in the original.

Two problems often exist with deep copy operations that don't exist with shallow copy operations:

- Recursive objects (compound objects that, directly or indirectly, contain a reference to themselves) may cause a recursive loop.
- Because deep copy copies everything it may copy too much, such as data which is intended to be shared between copies.

The `deepcopy()` function avoids these problems by:

- keeping a “memo” dictionary of objects already copied during the current copying pass; and
- letting user-defined classes override the copying operation or the set of components copied.

This module does not copy types like module, method, stack trace, stack frame, file, socket, window, array, or any similar types. It does “copy” functions and classes (shallow and deeply), by returning the original object unchanged; this is compatible with the way these are treated by the `pickle` module.

Shallow copies of dictionaries can be made using `dict.copy()`, and of lists by assigning a slice of the entire list, for example, `copied_list = original_list[:]`.

Changed in version 2.5: Added copying functions.

Classes can use the same interfaces to control copying that they use to control pickling. See the description of module `pickle` for information on these methods. The `copy` module does not use the `copy_reg` registration module.

In order for a class to define its own copy implementation, it can define special methods `__copy__()` and `__deepcopy__()`. The former is called to implement the shallow copy operation; no additional arguments are passed. The latter is called to implement the deep copy operation; it is passed one argument, the memo dictionary. If the `__deepcopy__()` implementation needs to make a deep copy of a component, it should call the `deepcopy()` function with the component as first argument and the memo dictionary as second argument.

See also:

Module `pickle` Discussion of the special methods used to support object state retrieval and restoration.

8.18 pprint — Data pretty printer

Source code: `Lib/pprint.py`

The `pprint` module provides a capability to “pretty-print” arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets, classes, or instances are included, as well as many other built-in objects which are not representable as Python constants.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width. Construct `PrettyPrinter` objects explicitly if you need to adjust the width constraint.

Changed in version 2.5: Dictionaries are sorted by key before the display is computed; before 2.5, a dictionary was sorted only if its display required more than one line, although that wasn't documented.

Changed in version 2.6: Added support for `set` and `frozenset`.

The `pprint` module defines one class:

class `pprint.PrettyPrinter` (*indent=1, width=80, depth=None, stream=None*)

Construct a `PrettyPrinter` instance. This constructor understands several keyword parameters. An output stream may be set using the `stream` keyword; the only method used on the stream object is the file protocol's `write()` method. If not specified, the `PrettyPrinter` adopts `sys.stdout`. Three additional parameters may be used to control the formatted representation. The keywords are *indent*, *depth*, and *width*. The amount of indentation added for each recursive level is specified by *indent*; the default is one. Other values can cause output to look a little odd, but can make nesting easier to spot. The number of levels which may be printed is controlled by *depth*; if the data structure being printed is too deep, the next contained level is replaced by `...`. By default, there is no constraint on the depth of the objects being formatted. The desired output width is constrained using the *width* parameter; the default is 80 characters. If a structure cannot be formatted within the constrained width, a best effort will be made.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[
    ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
    'spam',
    'eggs',
    'lumberjack',
    'knights',
    'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',)))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...)))))))
```

The `PrettyPrinter` class supports several derivative functions:

`pprint.pformat` (*object, indent=1, width=80, depth=None*)

Return the formatted representation of *object* as a string. *indent*, *width* and *depth* will be passed to the `PrettyPrinter` constructor as formatting parameters.

Changed in version 2.4: The parameters *indent*, *width* and *depth* were added.

`pprint.pprint` (*object, stream=None, indent=1, width=80, depth=None*)

Prints the formatted representation of *object* on *stream*, followed by a newline. If *stream* is `None`, `sys.stdout` is used. This may be used in the interactive interpreter instead of a `print` statement for inspecting values. *indent*, *width* and *depth* will be passed to the `PrettyPrinter` constructor as formatting parameters.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pprint(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
```

(continues on next page)

(continued from previous page)

```
'lumberjack',
'knights',
'ni']
```

Changed in version 2.4: The parameters *indent*, *width* and *depth* were added.

`pprint.isreadable(object)`

Determine if the formatted representation of *object* is “readable,” or can be used to reconstruct the value using `eval()`. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation.

One more support function is also defined:

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursive data structures. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"[<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni']"
```

8.18.1 PrettyPrinter Objects

`PrettyPrinter` instances have the following methods:

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the `PrettyPrinter` constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new `PrettyPrinter` objects don’t need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is “readable,” or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the *depth* parameter of the `PrettyPrinter` is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the `saferepr()` implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the `id()` of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the `format()` method

should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be 0 if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

New in version 2.3.

8.18.2 pprint Example

This example demonstrates several uses of the `pprint()` function and its parameters.

```
>>> import pprint
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',)))))))
>>> stuff = ['a' * 10, tup, ['a' * 30, 'b' * 30], ['c' * 20, 'd' * 20]]
>>> pprint.pprint(stuff)
['aaaaaaaaaa',
 ('spam',
 ('eggs',
 ('lumberjack',
 ('knights', ('ni', ('dead', ('parrot', ('fresh fruit',))))))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaaa', 'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddd']]
>>> pprint.pprint(stuff, depth=3)
['aaaaaaaaaa',
 ('spam', ('eggs', (...))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaaa', 'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddd']]
>>> pprint.pprint(stuff, width=60)
['aaaaaaaaaa',
 ('spam',
 ('eggs',
 ('lumberjack',
 ('knights',
 ('ni', ('dead', ('parrot', ('fresh fruit',))))))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaaa',
 'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddd']]
```

8.19 repr — Alternate repr() implementation

Note: The `repr` module has been renamed to `reprlib` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

Source code: [Lib/repr.py](#)

The `repr` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

class repr.Repr

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

repr.aRepr

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

repr.repr(obj)

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

8.19.1 Repr Objects

`Repr` instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

Repr.maxlevel

Depth limit on the creation of recursive representations. The default is 6.

Repr.maxdict**Repr.maxlist****Repr.maxtuple****Repr.maxset****Repr.maxfrozenset****Repr.maxdeque****Repr.maxarray**

Limits on the number of entries represented for the named object type. The default is 4 for `maxdict`, 5 for `maxarray`, and 6 for the others.

New in version 2.4: `maxset`, `maxfrozenset`, and `set`.

Repr.maxlong

Maximum number of characters in the representation for a long integer. Digits are dropped from the middle. The default is 40.

Repr.maxstring

Limit on the number of characters in the representation of the string. Note that the “normal” representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

Repr.maxother

This limit is used to control the size of object types for which no specific formatting method is available on the `Repr` object. It is applied in a similar manner as `maxstring`. The default is 20.

Repr.repr(obj)

The equivalent to the built-in `repr()` that uses the formatting imposed by the instance.

Repr.repr1(obj, level)

Recursive implementation used by `repr()`. This uses the type of `obj` to determine which formatting method to call, passing it `obj` and `level`. The type-specific methods should call `repr1()` to perform recursive formatting, with `level - 1` for the value of `level` in the recursive call.

Repr.repr_TYPE(obj, level)

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, `TYPE` is replaced by `string.join(string.split(type(obj).__name__, '_'))`. Dispatch to these methods is handled by `repr1()`. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

8.19.2 Subclassing Repr Objects

The use of dynamic dispatching by `Repr.repr1()` allows subclasses of `Repr` to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import repr as reprlib
import sys

class MyRepr(reprlib.Repr):
    def repr_file(self, obj, level):
        if obj.name in ['<stdin>', '<stdout>', '<stderr>']:
            return obj.name
        else:
            return repr(obj)

aRepr = MyRepr()
print aRepr.repr(sys.stdin)          # prints '<stdin>'
```

NUMERIC AND MATHEMATICAL MODULES

The modules described in this chapter provide numeric and math-related functions and data types. The `numbers` module defines an abstract hierarchy of numeric types. The `math` and `cmath` modules contain various mathematical functions for floating-point and complex numbers. For users more interested in decimal accuracy than in speed, the `decimal` module supports exact representations of decimal numbers.

The following modules are documented in this chapter:

9.1 `numbers` — Numeric abstract base classes

New in version 2.6.

The `numbers` module ([PEP 3141](#)) defines a hierarchy of numeric *abstract base classes* which progressively define more operations. None of the types defined in this module can be instantiated.

class `numbers.Number`

The root of the numeric hierarchy. If you just want to check if an argument *x* is a number, without caring what kind, use `isinstance(x, Number)`.

9.1.1 The numeric tower

class `numbers.Complex`

Subclasses of this type describe complex numbers and include the operations that work on the built-in `complex` type. These are: conversions to `complex` and `bool`, `real`, `imag`, `+`, `-`, `*`, `/`, `abs()`, `conjugate()`, `==`, and `!=`. All except `-` and `!=` are abstract.

real

Abstract. Retrieves the real component of this number.

imag

Abstract. Retrieves the imaginary component of this number.

conjugate()

Abstract. Returns the complex conjugate. For example, `(1+3j).conjugate() == (1-3j)`.

class `numbers.Real`

To `Complex`, `Real` adds the operations that work on real numbers.

In short, those are: a conversion to `float`, `math.trunc()`, `round()`, `math.floor()`, `math.ceil()`, `divmod()`, `//`, `%`, `<`, `<=`, `>`, and `>=`.

Real also provides defaults for `complex()`, `real`, `imag`, and `conjugate()`.

class `numbers.Rational`

Subtypes *Real* and adds *numerator* and *denominator* properties, which should be in lowest terms. With these, it provides a default for *float()*.

numerator
Abstract.

denominator
Abstract.

class `numbers.Integral`

Subtypes *Rational* and adds a conversion to *int*. Provides defaults for *float()*, *numerator*, and *denominator*. Adds abstract methods for **** and bit-string operations: *<<*, *>>*, *&*, *^*, *|*, *~*.

9.1.2 Notes for type implementors

Implementors should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two different extensions of the real numbers. For example, *fractions.Fraction* implements *hash()* as follows:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add *MyFoo* between *Complex* and *Real* with:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built in type and do the operation there. For subtypes of *Integral*, this means that *__add__()* and *__radd__()* should be defined as:

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(self, other)
```

(continues on next page)

(continued from previous page)

```

    else:
        return NotImplemented

def __radd__(self, other):
    if isinstance(other, MyIntegral):
        return do_my_adding_stuff(other, self)
    elif isinstance(other, OtherTypeIKnowAbout):
        return do_my_other_adding_stuff(other, self)
    elif isinstance(other, Integral):
        return int(other) + int(self)
    elif isinstance(other, Real):
        return float(other) + float(self)
    elif isinstance(other, Complex):
        return complex(other) + complex(self)
    else:
        return NotImplemented

```

There are 5 different cases for a mixed-type operation on subclasses of `Complex`. I'll refer to all of the above code that doesn't refer to `MyIntegral` and `OtherTypeIKnowAbout` as “boilerplate”. `a` will be an instance of `A`, which is a subtype of `Complex` (`a : A <: Complex`), and `b : B <: Complex`. I'll consider `a + b`:

1. If `A` defines an `__add__()` which accepts `b`, all is well.
2. If `A` falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that `B` defines a more intelligent `__radd__()`, so the boilerplate should return `NotImplemented` from `__add__()`. (Or `A` may not implement `__add__()` at all.)
3. Then `B`'s `__radd__()` gets a chance. If it accepts `a`, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If `B <: A`, Python tries `B.__radd__` before `A.__add__`. This is ok, because it was implemented with knowledge of `A`, so it can handle those instances before delegating to `Complex`.

If `A <: Complex` and `B <: Real` without sharing any other knowledge, then the appropriate shared operation is the one involving the built in `complex`, and both `__radd__()`s land there, so `a+b == b+a`.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, `fractions.Fraction` uses:

```

def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, long, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'
    forward.__doc__ = monomorphic_operator.__doc__

    def reverse(b, a):
        if isinstance(a, Rational):
            # Includes ints.
            return monomorphic_operator(a, b)

```

(continues on next page)

(continued from previous page)

```

    elif isinstance(a, numbers.Real):
        return fallback_operator(float(a), float(b))
    elif isinstance(a, numbers.Complex):
        return fallback_operator(complex(a), complex(b))
    else:
        return NotImplemented
reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
reverse.__doc__ = monomorphic_operator.__doc__

return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...

```

9.2 math — Mathematical functions

This module is always available. It provides access to the mathematical functions defined by the C standard.

These functions cannot be used with complex numbers; use the functions of the same name from the `cmath` module if you require support for complex numbers. The distinction between functions which support complex numbers and those which don't is made since most users do not want to learn quite as much mathematics as required to understand complex numbers. Receiving an exception instead of a complex result allows earlier detection of the unexpected complex number used as a parameter, so that the programmer can determine how and why it was generated in the first place.

The following functions are provided by this module. Except when explicitly noted otherwise, all return values are floats.

9.2.1 Number-theoretic and representation functions

`math.ceil(x)`

Return the ceiling of x as a float, the smallest integer value greater than or equal to x .

`math.copysign(x, y)`

Return x with the sign of y . On a platform that supports signed zeros, `copysign(1.0, -0.0)` returns `-1.0`.

New in version 2.6.

`math.fabs(x)`

Return the absolute value of x .

`math.factorial(x)`

Return x factorial. Raises `ValueError` if x is not integral or is negative.

New in version 2.6.

`math.floor(x)`

Return the floor of x as a float, the largest integer value less than or equal to x .

`math.fmod(x, y)`

Return `fmod(x, y)`, as defined by the platform C library. Note that the Python expression `x % y` may not

return the same result. The intent of the C standard is that `fmod(x, y)` be exactly (mathematically; to infinite precision) equal to $x - n*y$ for some integer n such that the result has the same sign as x and magnitude less than `abs(y)`. Python's `x % y` returns a result with the sign of y instead, and may not be exactly computable for float arguments. For example, `fmod(-1e-100, 1e100)` is $-1e-100$, but the result of Python's $-1e-100 \% 1e100$ is $1e100 - 1e-100$, which cannot be represented exactly as a float, and rounds to the surprising $1e100$. For this reason, function `fmod()` is generally preferred when working with floats, while Python's `x % y` is preferred when working with integers.

`math.frexp(x)`

Return the mantissa and exponent of x as the pair (m, e) . m is a float and e is an integer such that $x == m * 2**e$ exactly. If x is zero, returns $(0.0, 0)$, otherwise $0.5 \leq \text{abs}(m) < 1$. This is used to “pick apart” the internal representation of a float in a portable way.

`math.fsum(iterable)`

Return an accurate floating point sum of values in the iterable. Avoids loss of precision by tracking multiple intermediate partial sums:

```
>>> sum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
0.9999999999999999
>>> fsum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
1.0
```

The algorithm's accuracy depends on IEEE-754 arithmetic guarantees and the typical case where the rounding mode is half-even. On some non-Windows builds, the underlying C library uses extended precision addition and may occasionally double-round an intermediate sum causing it to be off in its least significant bit.

For further discussion and two alternative approaches, see the [ASPN cookbook recipes for accurate floating point summation](#).

New in version 2.6.

`math.isinf(x)`

Check if the float x is positive or negative infinity.

New in version 2.6.

`math.isnan(x)`

Check if the float x is a NaN (not a number). For more information on NaNs, see the IEEE 754 standards.

New in version 2.6.

`math.ldexp(x, i)`

Return $x * (2**i)$. This is essentially the inverse of function `frexp()`.

`math.modf(x)`

Return the fractional and integer parts of x . Both results carry the sign of x and are floats.

`math.trunc(x)`

Return the *Real* value x truncated to an *Integral* (usually a long integer). Uses the `__trunc__` method.

New in version 2.6.

Note that `frexp()` and `modf()` have a different call/return pattern than their C equivalents: they take a single argument and return a pair of values, rather than returning their second return value through an ‘output parameter’ (there is no such thing in Python).

For the `ceil()`, `floor()`, and `modf()` functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float x with `abs(x) >= 2**52` necessarily has no fractional bits.

9.2.2 Power and logarithmic functions

`math.exp(x)`
Return e^{**x} .

`math.expm1(x)`
Return $e^{**x} - 1$. For small floats x , the subtraction in $\text{exp}(x) - 1$ can result in a significant loss of precision; the `expm1()` function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precision
1.0000050000166668e-05
```

New in version 2.7.

`math.log(x[, base])`
With one argument, return the natural logarithm of x (to base e).
With two arguments, return the logarithm of x to the given *base*, calculated as $\log(x) / \log(\text{base})$.

Changed in version 2.3: *base* argument added.

`math.log1p(x)`
Return the natural logarithm of $1+x$ (base e). The result is calculated in a way which is accurate for x near zero.

New in version 2.6.

`math.log10(x)`
Return the base-10 logarithm of x . This is usually more accurate than $\log(x, 10)$.

`math.pow(x, y)`
Return x raised to the power y . Exceptional cases follow Annex ‘F’ of the C99 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when x is a zero or a NaN. If both x and y are finite, x is negative, and y is not an integer then `pow(x, y)` is undefined, and raises `ValueError`.

Unlike the built-in `**` operator, `math.pow()` converts both its arguments to type `float`. Use `**` or the built-in `pow()` function for computing exact integer powers.

Changed in version 2.6: The outcome of `1**nan` and `nan**0` was undefined.

`math.sqrt(x)`
Return the square root of x .

9.2.3 Trigonometric functions

`math.acos(x)`
Return the arc cosine of x , in radians.

`math.asin(x)`
Return the arc sine of x , in radians.

`math.atan(x)`
Return the arc tangent of x , in radians.

`math.atan2(y, x)`
Return $\text{atan}(y / x)$, in radians. The result is between $-\pi$ and π . The vector in the plane from the origin to point (x, y) makes this angle with the positive X axis. The point of `atan2()` is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both $\pi/4$, but `atan2(-1, -1)` is $-3\pi/4$.

`math.cos(x)`

Return the cosine of x radians.

`math.hypot(x, y)`

Return the Euclidean norm, `sqrt(x*x + y*y)`. This is the length of the vector from the origin to point (x, y) .

`math.sin(x)`

Return the sine of x radians.

`math.tan(x)`

Return the tangent of x radians.

9.2.4 Angular conversion

`math.degrees(x)`

Convert angle x from radians to degrees.

`math.radians(x)`

Convert angle x from degrees to radians.

9.2.5 Hyperbolic functions

`math.acosh(x)`

Return the inverse hyperbolic cosine of x .

New in version 2.6.

`math.asinh(x)`

Return the inverse hyperbolic sine of x .

New in version 2.6.

`math.atanh(x)`

Return the inverse hyperbolic tangent of x .

New in version 2.6.

`math.cosh(x)`

Return the hyperbolic cosine of x .

`math.sinh(x)`

Return the hyperbolic sine of x .

`math.tanh(x)`

Return the hyperbolic tangent of x .

9.2.6 Special functions

`math.erf(x)`

Return the error function at x .

New in version 2.7.

`math.erfc(x)`

Return the complementary error function at x .

New in version 2.7.

`math.gamma(x)`

Return the Gamma function at x .

New in version 2.7.

`math.lgamma(x)`

Return the natural logarithm of the absolute value of the Gamma function at x .

New in version 2.7.

9.2.7 Constants

`math.pi`

The mathematical constant $\pi = 3.141592\dots$, to available precision.

`math.e`

The mathematical constant $e = 2.718281\dots$, to available precision.

CPython implementation detail: The `math` module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise `ValueError` for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and `OverflowError` for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

Changed in version 2.6: Behavior in special cases now aims to follow C99 Annex F. In earlier versions of Python the behavior in special cases was loosely specified.

Module `cmath` Complex number versions of many of these functions.

9.3 `cmath` — Mathematical functions for complex numbers

This module is always available. It provides access to mathematical functions for complex numbers. The functions in this module accept integers, floating-point numbers or complex numbers as arguments. They will also accept any Python object that has either a `__complex__()` or a `__float__()` method: these methods are used to convert the object to a complex or floating-point number, respectively, and the function is then applied to the result of the conversion.

Note: On platforms with hardware and system-level support for signed zeros, functions involving branch cuts are continuous on *both* sides of the branch cut: the sign of the zero distinguishes one side of the branch cut from the other. On platforms that do not support signed zeros the continuity is as specified below.

9.3.1 Conversions to and from polar coordinates

A Python complex number z is stored internally using *rectangular* or *Cartesian* coordinates. It is completely determined by its *real part* `z.real` and its *imaginary part* `z.imag`. In other words:

```
z == z.real + z.imag*1j
```

Polar coordinates give an alternative way to represent a complex number. In polar coordinates, a complex number z is defined by the modulus r and the phase angle ϕ . The modulus r is the distance from z to the origin, while the phase ϕ is the counterclockwise angle, measured in radians, from the positive x-axis to the line segment that joins the origin to z .

The following functions can be used to convert from the native rectangular coordinates to polar coordinates and back.

`cmath.phase(x)`

Return the phase of x (also known as the *argument* of x), as a float. `phase(x)` is equivalent to `math.atan2(x.imag, x.real)`. The result lies in the range $[-\pi, \pi]$, and the branch cut for this operation lies along the negative real axis, continuous from above. On systems with support for signed zeros (which includes most systems in current use), this means that the sign of the result is the same as the sign of `x.imag`, even when `x.imag` is zero:

```
>>> phase(complex(-1.0, 0.0))
3.1415926535897931
>>> phase(complex(-1.0, -0.0))
-3.1415926535897931
```

New in version 2.6.

Note: The modulus (absolute value) of a complex number x can be computed using the built-in `abs()` function. There is no separate `cmath` module function for this operation.

`cmath.polar(x)`

Return the representation of x in polar coordinates. Returns a pair (r, ϕ) where r is the modulus of x and ϕ is the phase of x . `polar(x)` is equivalent to `(abs(x), phase(x))`.

New in version 2.6.

`cmath.rect(r, phi)`

Return the complex number x with polar coordinates r and ϕ . Equivalent to `r * (math.cos(phi) + math.sin(phi)*1j)`.

New in version 2.6.

9.3.2 Power and logarithmic functions

`cmath.exp(x)`

Return the exponential value e^{**x} .

`cmath.log(x[, base])`

Returns the logarithm of x to the given *base*. If the *base* is not specified, returns the natural logarithm of x . There is one branch cut, from 0 along the negative real axis to $-\infty$, continuous from above.

Changed in version 2.4: *base* argument added.

`cmath.log10(x)`

Return the base-10 logarithm of x . This has the same branch cut as `log()`.

`cmath.sqrt(x)`

Return the square root of x . This has the same branch cut as `log()`.

9.3.3 Trigonometric functions

`cmath.acos(x)`

Return the arc cosine of x . There are two branch cuts: One extends right from 1 along the real axis to ∞ , continuous from below. The other extends left from -1 along the real axis to $-\infty$, continuous from above.

`cmath.asin(x)`

Return the arc sine of x . This has the same branch cuts as `acos()`.

`cmath.atan(x)`

Return the arc tangent of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

Changed in version 2.6: direction of continuity of upper cut reversed

`cmath.cos(x)`

Return the cosine of x .

`cmath.sin(x)`

Return the sine of x .

`cmath.tan(x)`

Return the tangent of x .

9.3.4 Hyperbolic functions

`cmath.acosh(x)`

Return the inverse hyperbolic cosine of x . There is one branch cut, extending left from 1 along the real axis to $-\infty$, continuous from above.

`cmath.asinh(x)`

Return the inverse hyperbolic sine of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

Changed in version 2.6: branch cuts moved to match those recommended by the C99 standard

`cmath.atanh(x)`

Return the inverse hyperbolic tangent of x . There are two branch cuts: One extends from 1 along the real axis to ∞ , continuous from below. The other extends from -1 along the real axis to $-\infty$, continuous from above.

Changed in version 2.6: direction of continuity of right cut reversed

`cmath.cosh(x)`

Return the hyperbolic cosine of x .

`cmath.sinh(x)`

Return the hyperbolic sine of x .

`cmath.tanh(x)`

Return the hyperbolic tangent of x .

9.3.5 Classification functions

`cmath.isinf(x)`

Return `True` if the real or the imaginary part of x is positive or negative infinity.

New in version 2.6.

`cmath.isnan(x)`

Return `True` if the real or imaginary part of `x` is not a number (NaN).

New in version 2.6.

9.3.6 Constants

`cmath.pi`

The mathematical constant π , as a float.

`cmath.e`

The mathematical constant e , as a float.

Note that the selection of functions is similar, but not identical, to that in module `math`. The reason for having two modules is that some users aren't interested in complex numbers, and perhaps don't even know what they are. They would rather have `math.sqrt(-1)` raise an exception than return a complex number. Also note that the functions defined in `cmath` always return a complex number, even if the answer can be expressed as a real number (in which case the complex number has an imaginary part of zero).

A note on branch cuts: They are curves along which the given function fails to be continuous. They are a necessary feature of many complex functions. It is assumed that if you need to compute with complex functions, you will understand about branch cuts. Consult almost any (not too elementary) book on complex variables for enlightenment. For information of the proper choice of branch cuts for numerical purposes, a good reference should be the following:

See also:

Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), *The state of the art in numerical analysis*. Clarendon Press (1987) pp165–211.

9.4 `decimal` — Decimal fixed point and floating point arithmetic

New in version 2.4.

The `decimal` module provides support for decimal floating point arithmetic. It offers several advantages over the `float` datatype:

- Decimal “is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle – computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school.” – excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like 1.1 and 2.2 do not have exact representations in binary floating point. End users typically would not expect `1.1 + 2.2` to display as `3.3000000000000003` as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point, `0.1 + 0.1 + 0.1 - 0.3` is exactly equal to zero. In binary floating point, the result is `5.5511151231257827e-017`. While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that `1.30 + 1.20` is `2.50`. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication, the “schoolbook” approach uses all the figures in the multiplicands. For instance, `1.3 * 1.2` gives `1.56` while `1.30 * 1.20` gives `1.5600`.
- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support “without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic.” – excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as `Infinity`, `-Infinity`, and `NaN`. The standard also differentiates `-0` from `+0`.

The context for arithmetic is an environment specifying precision, rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include `ROUND_CEILING`, `ROUND_DOWN`, `ROUND_FLOOR`, `ROUND_HALF_DOWN`, `ROUND_HALF_EVEN`, `ROUND_HALF_UP`, `ROUND_UP`, and `ROUND_05UP`.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: *Clamped*, *InvalidOperation*, *DivisionByZero*, *Inexact*, *Rounded*, *Subnormal*, *Overflow*, and *Underflow*.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

See also:

- IBM’s General Decimal Arithmetic Specification, [The General Decimal Arithmetic Specification](#).

9.4.1 Quick-start Tutorial

The usual start to using decimals is importing the module, viewing the current context with `getcontext()` and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
       capitals=1, flags=[], traps=[Overflow, DivisionByZero,
       InvalidOperation])
>>> getcontext().prec = 7           # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as `NaN` which stands for “Not a number”, positive and negative `Infinity`, and `-0`.

```

>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.140000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.41421356237')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')

```

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```

>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')

```

Decimals interact well with much of the rest of Python. Here is a small decimal floating point flying circus:

```

>>> data = map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split())
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)      # round() first converts to binary floating point
1.3
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')

```

(continues on next page)

(continued from previous page)

```
>>> c % a
Decimal('0.77')
```

And some mathematical functions are also available to Decimal:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')
```

The `quantize()` method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

As shown above, the `getcontext()` function accesses the current context and allows the settings to be changed. This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the `Context()` constructor. To make an alternate active, use the `setcontext()` function.

In accordance with the standard, the `decimal` module provides two ready to use standard contexts, `BasicContext` and `ExtendedContext`. The former is especially useful for debugging because many of the traps are enabled:

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
       capitals=1, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the `clear_flags()` method.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
        capitals=1, flags=[Rounded, Inexact], traps=[])
```

The *flags* entry shows that the rational approximation to *Pi* was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the *traps* field of a context:

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to *Decimal* with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

9.4.2 Decimal objects

class decimal.*Decimal* ([*value* [, *context*]])

Construct a new *Decimal* object based from *value*.

value can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns *Decimal*('0'). If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters are removed:

```
sign          ::= '+' | '-'
digit         ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator     ::= 'e' | 'E'
digits        ::= digit [digit]...
decimal-part  ::= digits '.' [digits] | ['.' ] digits
exponent-part ::= indicator [sign] digits
infinity      ::= 'Infinity' | 'Inf'
nan           ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] | infinity
numeric-string ::= [sign] numeric-value | [sign] nan
```

If *value* is a unicode string then other Unicode decimal digits are also permitted where *digit* appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `u'\uff10'` through `u'\uff19'`.

If *value* is a *tuple*, it should have three components, a sign (0 for positive or 1 for negative), a *tuple* of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a *float*, the binary floating point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.100000000000000088817841970012523233890533447265625')`.

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps *InvalidOperation*, an exception is raised; otherwise, the constructor returns a new *Decimal* with the value of NaN.

Once constructed, *Decimal* objects are immutable.

Changed in version 2.6: leading and trailing whitespace characters are permitted when creating a *Decimal* instance from a string.

Changed in version 2.7: The argument to the constructor is now permitted to be a *float* instance.

Decimal floating point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *long*).

There are some small differences between arithmetic on *Decimal* objects and arithmetic on integers and floats. When the remainder operator `%` is applied to *Decimal* objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity $x == (x // y) * y + x \% y$:

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the remainder and divide-integer operations (respectively) as described in the specification.

Decimal objects cannot generally be combined with floats in arithmetic operations: an attempt to add a *Decimal* to a *float*, for example, will raise a *TypeError*. There's one exception to this rule: it's possible to use Python's comparison operators to compare a *float* instance *x* with a *Decimal* instance *y*. Without this exception, comparisons between *Decimal* and *float* instances would follow the general rules for comparing objects of different types described in the expressions section of the reference manual, leading to confusing results.

Changed in version 2.7: A comparison between a *float* instance *x* and a *Decimal* instance *y* now returns a result based on the values of *x* and *y*. In earlier versions `x < y` returned the same (arbitrary) result for any *Decimal* instance *x* and any *float* instance *y*.

In addition to the standard numeric properties, decimal floating point objects also have a number of specialized methods:

adjusted()

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

as_tuple()

Return a *named tuple* representation of the number: `DecimalTuple(sign, digits, exponent)`.

Changed in version 2.6: Use a named tuple.

canonical()

Return the canonical encoding of the argument. Currently, the encoding of a *Decimal* instance is always canonical, so this operation returns its argument unchanged.

New in version 2.6.

compare(*other*[, *context*])

Compare the values of two *Decimal* instances. This operation behaves in the same way as the usual comparison method `__cmp__()`, except that *compare()* returns a *Decimal* instance rather than an integer, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN ==> Decimal('NaN')
a < b           ==> Decimal('-1')
a == b         ==> Decimal('0')
a > b           ==> Decimal('1')
```

compare_signal(*other*[, *context*])

This operation is identical to the *compare()* method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

New in version 2.6.

compare_total(*other*)

Compare two operands using their abstract representation rather than their numerical value. Similar to the *compare()* method, but the result gives a total ordering on *Decimal* instances. Two *Decimal* instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is *Decimal('0')* if both operands have the same representation, *Decimal('-1')* if the first operand is lower in the total order than the second, and *Decimal('1')* if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

New in version 2.6.

compare_total_mag(*other*)

Compare two operands using their abstract representation rather than their value as in *compare_total()*, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

New in version 2.6.

conjugate()

Just returns self, this method is only to comply with the Decimal Specification.

New in version 2.6.

copy_abs()

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

New in version 2.6.

copy_negate()

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

New in version 2.6.

copy_sign(*other*)

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

New in version 2.6.

exp([*context*])

Return the value of the (natural) exponential function e^{**x} at the given number. The result is correctly rounded using the ROUND_HALF_EVEN rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

New in version 2.6.

from_float(*f*)

Classmethod that converts a float to a decimal number, exactly.

Note *Decimal.from_float(0.1)* is not the same as *Decimal('0.1')*. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is $0x1.999999999999p-4$. That equivalent value in decimal is $0.100000000000000055511151231257827021181583404541015625$.

Note: From Python 2.7 onwards, a *Decimal* instance can also be constructed directly from a *float*.

```
>>> Decimal.from_float(0.1)
Decimal('0.100000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

New in version 2.7.

fma(*other*, *third*[, *context*])

Fused multiply-add. Return $\text{self} * \text{other} + \text{third}$ with no rounding of the intermediate product $\text{self} * \text{other}$.

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

New in version 2.6.

is_canonical()

Return *True* if the argument is canonical and *False* otherwise. Currently, a *Decimal* instance is always canonical, so this operation always returns *True*.

New in version 2.6.

is_finite()

Return *True* if the argument is a finite number, and *False* if the argument is an infinity or a NaN.

New in version 2.6.

is_infinite()

Return *True* if the argument is either positive or negative infinity and *False* otherwise.

New in version 2.6.

is_nan()

Return *True* if the argument is a (quiet or signaling) NaN and *False* otherwise.

New in version 2.6.

is_normal()

Return *True* if the argument is a *normal* finite non-zero number with an adjusted exponent greater than or equal to *Emin*. Return *False* if the argument is zero, subnormal, infinite or a NaN. Note, the term *normal* is used here in a different sense with the *normalize()* method which is used to create canonical values.

New in version 2.6.

is_qnan()

Return *True* if the argument is a quiet NaN, and *False* otherwise.

New in version 2.6.

is_signed()

Return *True* if the argument has a negative sign and *False* otherwise. Note that zeros and NaNs can both carry signs.

New in version 2.6.

is_snan()

Return *True* if the argument is a signaling NaN and *False* otherwise.

New in version 2.6.

is_subnormal()

Return *True* if the argument is subnormal, and *False* otherwise. A number is subnormal is if it is nonzero, finite, and has an adjusted exponent less than *Emin*.

New in version 2.6.

is_zero()

Return *True* if the argument is a (positive or negative) zero and *False* otherwise.

New in version 2.6.

ln([context])

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the ROUND_HALF_EVEN rounding mode.

New in version 2.6.

log10([context])

Return the base ten logarithm of the operand. The result is correctly rounded using the ROUND_HALF_EVEN rounding mode.

New in version 2.6.

logb([context])

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the operand is a zero then *Decimal('Infinity')* is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then *Decimal('Infinity')* is returned.

New in version 2.6.

logical_and (*other* [, *context*])

logical_and() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise *and* of the two operands.

New in version 2.6.

logical_invert ([*context*])

logical_invert() is a logical operation. The result is the digit-wise inversion of the operand.

New in version 2.6.

logical_or (*other* [, *context*])

logical_or() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise *or* of the two operands.

New in version 2.6.

logical_xor (*other* [, *context*])

logical_xor() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

New in version 2.6.

max (*other* [, *context*])

Like *max(self, other)* except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

max_mag (*other* [, *context*])

Similar to the *max()* method, but the comparison is done using the absolute values of the operands.

New in version 2.6.

min (*other* [, *context*])

Like *min(self, other)* except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

min_mag (*other* [, *context*])

Similar to the *min()* method, but the comparison is done using the absolute values of the operands.

New in version 2.6.

next_minus ([*context*])

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

New in version 2.6.

next_plus ([*context*])

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

New in version 2.6.

next_toward (*other* [, *context*])

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

New in version 2.6.

normalize ([*context*])

Normalize the number by stripping the rightmost trailing zeros and converting any result equal to

`Decimal('0')` to `Decimal('0e0')`. Used for producing canonical values for attributes of an equivalence class. For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

number_class (*[context]*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

New in version 2.6.

quantize (*exp* [, *rounding* [, *context* [, *watchexp*]]])

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the *rounding* argument if given, else by the given *context* argument; if neither argument is given the rounding mode of the current thread's context is used.

If *watchexp* is set (default), then an error is returned whenever the resulting exponent is greater than *E_{max}* or less than *E_{tiny}*.

radix ()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

New in version 2.6.

remainder_near (*other* [, *context*])

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where *n* is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

rotate (*other* [, *context*])

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

New in version 2.6.

same_quantum (*other* [, *context*])

Test whether self and other have the same exponent or whether both are NaN.

scaleb (*other* [, *context*])

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by $10^{**other}$. The second operand must be an integer.

New in version 2.6.

shift (*other* [, *context*])

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

New in version 2.6.

sqrt ([*context*])

Return the square root of the argument to full precision.

to_eng_string ([*context*])

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

to_integral ([*rounding* [, *context*]])

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

to_integral_exact ([*rounding* [, *context*]])

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

New in version 2.6.

to_integral_value ([*rounding* [, *context*]])

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Changed in version 2.6: renamed from `to_integral` to `to_integral_value`. The old name remains valid for compatibility.

Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions:

`decimal.getcontext()`
Return the current context for the active thread.

`decimal.setcontext(c)`
Set the current context for the active thread to *c*.

Beginning with Python 2.5, you can also use the `with` statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext([c])`
Return a context manager that will set the current context for the active thread to a copy of *c* on entry to the `with`-statement and restore the previous context when exiting the `with`-statement. If no context is specified, a copy of the current context is used.

New in version 2.5.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42    # Perform a high precision calculation
    s = calculate_something()
s = +s    # Round the final result back to the default precision

with localcontext(BasicContext):    # temporarily use the BasicContext
    print Decimal(1) / Decimal(7)
    print Decimal(355) / Decimal(113)
```

New contexts can also be created using the `Context` constructor described below. In addition, the module provides three pre-made contexts:

class `decimal.BasicContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_UP`. All flags are cleared. All traps are enabled (treated as exceptions) except *Inexact*, *Rounded*, and *Subnormal*.

Because many of the traps are enabled, this context is useful for debugging.

class decimal.ExtendedContext

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of `NaN` or `Infinity` instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

class decimal.DefaultContext

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such as precision) has the effect of changing the default for new contexts created by the `Context` constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are precision=28, rounding=`ROUND_HALF_EVEN`, and enabled traps for Overflow, Invalid-Operation, and DivisionByZero.

In addition to the three supplied contexts, new contexts can be created with the `Context` constructor.

class decimal.Context (*prec=None, rounding=None, traps=None, flags=None, Emin=None, Emax=None, capitals=1*)

Creates a new context. If a field is not specified or is `None`, the default values are copied from the `DefaultContext`. If the `flags` field is not specified or is `None`, all flags are cleared.

The `prec` field is a positive integer that sets the precision for arithmetic operations in the context.

The `rounding` option is one of:

- `ROUND_CEILING` (towards `Infinity`),
- `ROUND_DOWN` (towards zero),
- `ROUND_FLOOR` (towards `-Infinity`),
- `ROUND_HALF_DOWN` (to nearest with ties going towards zero),
- `ROUND_HALF_EVEN` (to nearest with ties going to nearest even integer),
- `ROUND_HALF_UP` (to nearest with ties going away from zero), or
- `ROUND_UP` (away from zero).
- `ROUND_05UP` (away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise towards zero)

The `traps` and `flags` fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The `Emin` and `Emax` fields are integers specifying the outer limits allowable for exponents.

The `capitals` field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

Changed in version 2.6: The `ROUND_05UP` rounding mode was added.

The `Context` class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the `Decimal` methods described above (with the exception of the `adjusted()` and `as_tuple()` methods) there is a corresponding `Context` method. For example, for a `Context` instance `C` and `Decimal` instance `x`, `C.exp(x)` is equivalent to `x.exp(context=C)`.

Each `Context` method accepts a Python integer (an instance of `int` or `long`) anywhere that a `Decimal` instance is accepted.

`clear_flags()`

Resets all of the flags to 0.

`copy()`

Return a duplicate of the context.

`copy_decimal(num)`

Return a copy of the `Decimal` instance `num`.

`create_decimal(num)`

Creates a new `Decimal` instance from `num` but using `self` as context. Unlike the `Decimal` constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace is permitted.

`create_decimal_from_float(f)`

Creates a new `Decimal` instance from a float `f` but rounding using `self` as the context. Unlike the `Decimal.from_float()` class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
Inexact: None
```

New in version 2.7.

`Etiny()`

Returns a value equal to $E_{\min} - \text{prec} + 1$ which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to `Etiny`.

`Etop()`

Returns a value equal to $E_{\max} - \text{prec} + 1$.

The usual approach to working with decimals is to create `Decimal` instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the `Decimal` class and are only briefly recounted here.

`abs(x)`

Returns the absolute value of `x`.

add (*x*, *y*)
Return the sum of *x* and *y*.

canonical (*x*)
Returns the same Decimal object *x*.

compare (*x*, *y*)
Compares *x* and *y* numerically.

compare_signal (*x*, *y*)
Compares the values of the two operands numerically.

compare_total (*x*, *y*)
Compares two operands using their abstract representation.

compare_total_mag (*x*, *y*)
Compares two operands using their abstract representation, ignoring sign.

copy_abs (*x*)
Returns a copy of *x* with the sign set to 0.

copy_negate (*x*)
Returns a copy of *x* with the sign inverted.

copy_sign (*x*, *y*)
Copies the sign from *y* to *x*.

divide (*x*, *y*)
Return *x* divided by *y*.

divide_int (*x*, *y*)
Return *x* divided by *y*, truncated to an integer.

divmod (*x*, *y*)
Divides two numbers and returns the integer part of the result.

exp (*x*)
Returns $e^{**}x$.

fma (*x*, *y*, *z*)
Returns *x* multiplied by *y*, plus *z*.

is_canonical (*x*)
Returns True if *x* is canonical; otherwise returns False.

is_finite (*x*)
Returns True if *x* is finite; otherwise returns False.

is_infinite (*x*)
Returns True if *x* is infinite; otherwise returns False.

is_nan (*x*)
Returns True if *x* is a qNaN or sNaN; otherwise returns False.

is_normal (*x*)
Returns True if *x* is a normal number; otherwise returns False.

is_qnan (*x*)
Returns True if *x* is a quiet NaN; otherwise returns False.

is_signed (*x*)
Returns True if *x* is negative; otherwise returns False.

is_snan (*x*)
Returns `True` if *x* is a signaling NaN; otherwise returns `False`.

is_subnormal (*x*)
Returns `True` if *x* is subnormal; otherwise returns `False`.

is_zero (*x*)
Returns `True` if *x* is a zero; otherwise returns `False`.

ln (*x*)
Returns the natural (base e) logarithm of *x*.

log10 (*x*)
Returns the base 10 logarithm of *x*.

logb (*x*)
Returns the exponent of the magnitude of the operand's MSD.

logical_and (*x*, *y*)
Applies the logical operation *and* between each operand's digits.

logical_invert (*x*)
Invert all the digits in *x*.

logical_or (*x*, *y*)
Applies the logical operation *or* between each operand's digits.

logical_xor (*x*, *y*)
Applies the logical operation *xor* between each operand's digits.

max (*x*, *y*)
Compares two values numerically and returns the maximum.

max_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

min (*x*, *y*)
Compares two values numerically and returns the minimum.

min_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

minus (*x*)
Minus corresponds to the unary prefix minus operator in Python.

multiply (*x*, *y*)
Return the product of *x* and *y*.

next_minus (*x*)
Returns the largest representable number smaller than *x*.

next_plus (*x*)
Returns the smallest representable number larger than *x*.

next_toward (*x*, *y*)
Returns the number closest to *x*, in direction towards *y*.

normalize (*x*)
Reduces *x* to its simplest form.

number_class (*x*)
Returns an indication of the class of *x*.

plus (*x*)

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

power (*x*, *y*[, *modulo*])

Return *x* to the power of *y*, reduced modulo *modulo* if given.

With two arguments, compute $x^{**}y$. If *x* is negative then *y* must be integral. The result will be inexact unless *y* is integral and the result is finite and can be expressed exactly in ‘precision’ digits. The result should always be correctly rounded, using the rounding mode of the current thread’s context.

With three arguments, compute $(x^{**}y) \% modulo$. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- *y* must be nonnegative
- at least one of *x* or *y* must be nonzero
- *modulo* must be nonzero and have at most ‘precision’ digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing $(x^{**}y) \% modulo$ with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of *x*, *y* and *modulo*. The result is always exact.

Changed in version 2.6: *y* may now be nonintegral in $x^{**}y$. Stricter requirements for the three-argument version.

quantize (*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

radix ()

Just returns 10, as this is Decimal, :)

remainder (*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

remainder_near (*x*, *y*)

Returns $x - y * n$, where *n* is the integer nearest the exact value of x / y (if the result is 0 then its sign will be the sign of *x*).

rotate (*x*, *y*)

Returns a rotated copy of *x*, *y* times.

same_quantum (*x*, *y*)

Returns `True` if the two operands have the same exponent.

scaleb (*x*, *y*)

Returns the first operand after adding the second value its exp.

shift (*x*, *y*)

Returns a shifted copy of *x*, *y* times.

sqrt (*x*)

Square root of a non-negative number to context precision.

subtract (*x*, *y*)

Return the difference between *x* and *y*.

to_eng_string(*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

to_integral_exact(*x*)

Rounds to an integer.

to_sci_string(*x*)

Converts a number to a string using scientific notation.

9.4.4 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

class decimal.Clamped

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's *Emin* and *Emax* limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

class decimal.DecimalException

Base class for other signals and a subclass of *ArithmeticError*.

class decimal.DivisionByZero

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns *Infinity* or *-Infinity* with the sign determined by the inputs to the calculation.

class decimal.Inexact

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

class decimal.InvalidOperation

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns NaN. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
x._rescale( non-integer )
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

class decimal.**Overflow**

Numerical overflow.

Indicates the exponent is larger than `Emax` after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

class decimal.**Rounded**

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding `5.00` to `5.0`). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

class decimal.**Subnormal**

Exponent was lower than `Emin` prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

class decimal.**Underflow**

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.StandardError)
  DecimalException
    Clamped
    DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
    Inexact
      Overflow(Inexact, Rounded)
      Underflow(Inexact, Rounded, Subnormal)
    InvalidOperation
    Rounded
    Subnormal
```

9.4.5 Floating Point Notes

Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent `0.1` exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal('11111113'), Decimal('-11111111'), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')
```

(continues on next page)

(continued from previous page)

```
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The `decimal` module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

Special values

The number system for the `decimal` module provides special values including NaN, sNaN, `-Infinity`, `Infinity`, and two zeros, `+0` and `-0`.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the `DivisionByZero` signal is not trapped. Likewise, when the `Overflow` signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return NaN, or if the `InvalidOperation` signal is trapped, raise an exception. For example, `0/0` returns NaN which means “not a number”. This variety of NaN is quiet and, once created, will flow through other computations always resulting in another NaN. This behavior can be useful for a series of computations that occasionally have missing inputs — it allows the calculation to proceed while flagging specific results as invalid.

A variant is sNaN which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python’s comparison operators can be a little surprising where a NaN is involved. A test for equality where one of the operands is a quiet or signaling NaN always returns `False` (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns `True`. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the `InvalidOperation` signal if either operand is a NaN, and return `False` if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a NaN were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the `compare()` and `compare-signal()` methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating point

representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-10000000026')
```

9.4.6 Working with threads

The `getcontext()` function accesses a different `Context` object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called `DefaultContext`. To control the defaults so that each thread will use the same values throughout the application, directly modify the `DefaultContext` object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
. . .
```

9.4.7 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the `Decimal` class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', space or blank
    neg:     optional sign for negative numbers: '-', '(', space or blank
    trailneg: optional trailing minus indicator: '- ', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
```

(continues on next page)

(continued from previous page)

```

'($1,234,567.89) '
>>> moneyfmt(Decimal(123456789), sep=' ')
'123 456 789.00'
>>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
'<0.02>'

"""
q = Decimal(10) ** -places      # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = map(str, digits)
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
    build(sep)
build(curr)
build(neg if sign else pos)
return ''.join(reversed(result))

def pi():
    """Compute Pi to the current precision.

    >>> print pi()
    3.141592653589793238462643383

    """
    getcontext().prec += 2 # extra digits for intermediate steps
    three = Decimal(3)     # substitute "three=3.0" for regular floats
    lasts, t, s, n, na, d, da = 0, three, 3, 1, 0, 0, 24
    while s != lasts:
        lasts = s
        n, na = n+na, na+8
        d, da = d+da, da+32
        t = (t * n) / d
        s += t
    getcontext().prec -= 2
    return +s                # unary plus applies the new precision

def exp(x):
    """Return e raised to the power of x. Result type matches input type.

    >>> print exp(Decimal(1))
    2.718281828459045235360287471
    >>> print exp(Decimal(2))
    7.389056098930650227230427461
    >>> print exp(2.0)

```

(continues on next page)

(continued from previous page)

```

7.38905609893

    getcontext().prec += 2
    i, lasts, s, fact, num, sign = 1, 0, x, 1, x, 1
    while s != lasts:
        lasts = s
        i += 2
        fact *= i * (i-1)
        num *= x * x

```

(continues on next page)

(continued from previous page)

```

    sign *= -1
    s += num / fact * sign
    getcontext().prec -= 2
    return +s

```

9.4.8 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The `quantize()` method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation:

```

>>> TWOPLACES = Decimal(10) ** -2           # same as Decimal('0.01')

```

```

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

```

```

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')

```

```

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
...
Inexact: None

```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step:

```

>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                           # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                           # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)      # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)      # And quantize division
Decimal('0.03')

```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)
```

```
>>> mul(a, b)                                     # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

Q. There are many ways to express the same value. The numbers 200, 200.000, 2E2, and 02E+4 all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing 5.0E+3 as 5000 keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeros, losing significance, but keeping the value unchanged:

```
def remove_exponent(d):
    '''Remove exponent and trailing zeros.

    >>> remove_exponent(Decimal('5E+3'))
    Decimal('5000')

    '''
    return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()
```

Q. Is there a way to convert a regular float to a *Decimal*?

A. Yes, any binary floating point number can be exactly expressed as a *Decimal* though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that “what you type is what you get”. A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the `Context.create_decimal()` method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

9.5 fractions — Rational numbers

New in version 2.6.

Source code: [Lib/fractions.py](#)

The `fractions` module provides support for rational number arithmetic.

A `Fraction` instance can be constructed from a pair of integers, from another rational number, or from a string.

```
class fractions.Fraction (numerator=0, denominator=1)
class fractions.Fraction (other_fraction)
class fractions.Fraction (float)
class fractions.Fraction (decimal)
class fractions.Fraction (string)
```

The first version requires that `numerator` and `denominator` are instances of `numbers.Rational` and returns a new `Fraction` instance with value `numerator/denominator`. If `denominator` is 0, it raises a `ZeroDivisionError`. The second version requires that `other_fraction` is an instance of `numbers.Rational` and returns a `Fraction` instance with the same value. The next two versions accept either a `float` or a `decimal.Decimal` instance, and return a `Fraction` instance with exactly the same value. Note that due to the usual issues with binary floating-point (see [tut-fp-issues](#)), the argument to `Fraction(1.1)` is not exactly equal to 11/10, and so `Fraction(1.1)` does *not* return `Fraction(11, 10)` as one might expect. (But see the documentation for the `limit_denominator()` method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional `sign` may be either '+' or '-' and `numerator` and `denominator` (if present) are strings of decimal digits. In addition, any string that represents a finite value and is accepted by the `float` constructor is also accepted by the `Fraction` constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
```

(continues on next page)

(continued from previous page)

```

Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)

```

The *Fraction* class inherits from the abstract base class *numbers.Rational*, and implements all of the methods and operations from that class. *Fraction* instances are hashable, and should be treated as immutable. In addition, *Fraction* has the following methods:

Changed in version 2.7: The *Fraction* constructor now accepts *float* and *decimal.Decimal* instances.

from_float (*flt*)

This class method constructs a *Fraction* representing the exact value of *flt*, which must be a *float*. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

Note: From Python 2.7 onwards, you can also construct a *Fraction* instance directly from a *float*.

from_decimal (*dec*)

This class method constructs a *Fraction* representing the exact value of *dec*, which must be a *decimal.Decimal*.

Note: From Python 2.7 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

limit_denominator (*max_denominator=1000000*)

Finds and returns the closest *Fraction* to *self* that has denominator at most *max_denominator*. This method is useful for finding rational approximations to a given floating-point number:

```

>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)

```

or for recovering a rational number that's represented as a float:

```

>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)

```

(continues on next page)

(continued from previous page)

```
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

`fractions.gcd(a, b)`

Return the greatest common divisor of the integers *a* and *b*. If either *a* or *b* is nonzero, then the absolute value of `gcd(a, b)` is the largest integer that divides both *a* and *b*. `gcd(a, b)` has the same sign as *b* if *b* is nonzero; otherwise it takes the sign of *a*. `gcd(0, 0)` returns 0.

Module `numbers` The abstract base classes making up the numeric tower.

9.6 random — Generate pseudo-random numbers

Source code: [Lib/random.py](#)

This module implements pseudo-random number generators for various distributions.

For integers, uniform selection from a range. For sequences, uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function `random()`, which generates a random float uniformly in the semi-open range [0.0, 1.0). Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats and has a period of $2^{19937}-1$. The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence. However, being completely deterministic, it is not suitable for all purposes, and is completely unsuitable for cryptographic purposes.

The functions supplied by this module are actually bound methods of a hidden instance of the `random.Random` class. You can instantiate your own instances of `Random` to get generators that don't share state. This is especially useful for multi-threaded programs, creating a different instance of `Random` for each thread, and using the `jumpahead()` method to make it likely that the generated sequences seen by each thread don't overlap.

Class `Random` can also be subclassed if you want to use a different basic generator of your own devising: in that case, override the `random()`, `seed()`, `getstate()`, `setstate()` and `jumpahead()` methods. Optionally, a new generator can supply a `getrandbits()` method — this allows `randrange()` to produce selections over an arbitrarily large range.

New in version 2.4: the `getrandbits()` method.

As an example of subclassing, the `random` module provides the `WichmannHill` class that implements an alternative generator in pure Python. The class provides a backward compatible way to reproduce results from earlier versions of Python, which used the Wichmann-Hill algorithm as the core generator. Note that this Wichmann-Hill generator can no longer be recommended: its period is too short by contemporary standards, and the sequence generated is known to fail some stringent randomness tests. See the references below for a recent variant that repairs these flaws.

Changed in version 2.3: MersenneTwister replaced Wichmann-Hill as the default generator.

The `random` module also provides the `SystemRandom` class which uses the system function `os.urandom()` to generate random numbers from sources provided by the operating system.

Warning: The pseudo-random generators of this module should not be used for security purposes. Use `os.urandom()` or `SystemRandom` if you require a cryptographically secure pseudo-random number generator.

Bookkeeping functions:

`random.seed(a=None)`

Initialize internal state of the random number generator.

`None` or no argument seeds from current time or from an operating system specific randomness source if available (see the `os.urandom()` function for details on availability).

If `a` is not `None` or an `int` or a `long`, then `hash(a)` is used instead. Note that the hash values for some types are nondeterministic when `PYTHONHASHSEED` is enabled.

Changed in version 2.4: formerly, operating system resources were not used.

`random.getstate()`

Return an object capturing the current internal state of the generator. This object can be passed to `setstate()` to restore the state.

New in version 2.1.

Changed in version 2.6: State values produced in Python 2.6 cannot be loaded into earlier versions.

`random.setstate(state)`

`state` should have been obtained from a previous call to `getstate()`, and `setstate()` restores the internal state of the generator to what it was at the time `getstate()` was called.

New in version 2.1.

`random.jumpahead(n)`

Change the internal state to one different from and likely far away from the current state. `n` is a non-negative integer which is used to scramble the current state vector. This is most useful in multi-threaded programs, in conjunction with multiple instances of the `Random` class: `setstate()` or `seed()` can be used to force all instances into the same internal state, and then `jumpahead()` can be used to force the instances' states far apart.

New in version 2.1.

Changed in version 2.3: Instead of jumping to a specific state, `n` steps ahead, `jumpahead(n)` jumps to another state likely to be separated by many steps.

`random.getrandbits(k)`

Returns a python `long` int with `k` random bits. This method is supplied with the MersenneTwister generator and some other generators may also provide it as an optional part of the API. When available, `getrandbits()` enables `randrange()` to handle arbitrarily large ranges.

New in version 2.4.

Functions for integers:

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

Return a randomly selected element from `range(start, stop, step)`. This is equivalent to `choice(range(start, stop, step))`, but doesn't actually build a range object.

New in version 1.5.2.

`random.randint(a, b)`

Return a random integer `N` such that `a <= N <= b`.

Functions for sequences:

`random.choice(seq)`

Return a random element from the non-empty sequence *seq*. If *seq* is empty, raises *IndexError*.

`random.shuffle(x[, random])`

Shuffle the sequence *x* in place. The optional argument *random* is a 0-argument function returning a random float in [0.0, 1.0); by default, this is the function `random()`.

Note that for even rather small `len(x)`, the total number of permutations of *x* is larger than the period of most random number generators; this implies that most permutations of a long sequence can never be generated.

`random.sample(population, k)`

Return a *k* length list of unique elements chosen from the population sequence. Used for random sampling without replacement.

New in version 2.3.

Returns a new list containing elements from the population while leaving the original population unchanged. The resulting list is in selection order so that all sub-slices will also be valid random samples. This allows raffle winners (the sample) to be partitioned into grand prize and second place winners (the subslices).

Members of the population need not be *hashable* or unique. If the population contains repeats, then each occurrence is a possible selection in the sample.

To choose a sample from a range of integers, use an `xrange()` object as an argument. This is especially fast and space efficient for sampling from a large population: `sample(xrange(10000000), 60)`.

The following functions generate specific real-valued distributions. Function parameters are named after the corresponding variables in the distribution's equation, as used in common mathematical practice; most of these equations can be found in any statistics text.

`random.random()`

Return the next random floating point number in the range [0.0, 1.0).

`random.uniform(a, b)`

Return a random floating point number *N* such that $a \leq N \leq b$ for $a \leq b$ and $b \leq N \leq a$ for $b < a$.

The end-point value *b* may or may not be included in the range depending on floating-point rounding in the equation $a + (b-a) * \text{random}()$.

`random.triangular(low, high, mode)`

Return a random floating point number *N* such that $\text{low} \leq N \leq \text{high}$ and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

New in version 2.6.

`random.betavariate(alpha, beta)`

Beta distribution. Conditions on the parameters are $\alpha > 0$ and $\beta > 0$. Returned values range between 0 and 1.

`random.expovariate(lambd)`

Exponential distribution. *lambd* is 1.0 divided by the desired mean. It should be nonzero. (The parameter would be called "lambda", but that is a reserved word in Python.) Returned values range from 0 to positive infinity if *lambd* is positive, and from negative infinity to 0 if *lambd* is negative.

`random.gammavariate(alpha, beta)`

Gamma distribution. (*Not* the gamma function!) Conditions on the parameters are $\alpha > 0$ and $\beta > 0$.

The probability distribution function is:

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \text{beta})}{\text{math.gamma}(\alpha) * \text{beta} ** \alpha}$$

`random.gauss(mu, sigma)`

Gaussian distribution. *mu* is the mean, and *sigma* is the standard deviation. This is slightly faster than the `normalvariate()` function defined below.

`random.lognormvariate(mu, sigma)`

Log normal distribution. If you take the natural logarithm of this distribution, you'll get a normal distribution with mean *mu* and standard deviation *sigma*. *mu* can have any value, and *sigma* must be greater than zero.

`random.normalvariate(mu, sigma)`

Normal distribution. *mu* is the mean, and *sigma* is the standard deviation.

`random.vonmisesvariate(mu, kappa)`

mu is the mean angle, expressed in radians between 0 and 2π , and *kappa* is the concentration parameter, which must be greater than or equal to zero. If *kappa* is equal to zero, this distribution reduces to a uniform random angle over the range 0 to 2π .

`random.paretovariate(alpha)`

Pareto distribution. *alpha* is the shape parameter.

`random.weibullvariate(alpha, beta)`

Weibull distribution. *alpha* is the scale parameter and *beta* is the shape parameter.

Alternative Generators:

class `random.WichmannHill([seed])`

Class that implements the Wichmann-Hill algorithm as the core generator. Has all of the same methods as `Random` plus the `whseed()` method described below. Because this class is implemented in pure Python, it is not threadsafe and may require locks between calls. The period of the generator is 6,953,607,871,644 which is small enough to require care that two independent random sequences do not overlap.

`random.whseed([x])`

This is obsolete, supplied for bit-level compatibility with versions of Python prior to 2.1. See `seed()` for details. `whseed()` does not guarantee that distinct integer arguments yield distinct internal states, and can yield no more than about 2^{24} distinct internal states in all.

class `random.SystemRandom([seed])`

Class that uses the `os.urandom()` function for generating random numbers from sources provided by the operating system. Not available on all systems. Does not rely on software state and sequences are not reproducible. Accordingly, the `seed()` and `jumpahead()` methods have no effect and are ignored. The `getstate()` and `setstate()` methods raise `NotImplementedError` if called.

New in version 2.4.

Examples of basic usage:

```
>>> random.random()           # Random float x, 0.0 <= x < 1.0
0.37444887175646646
>>> random.uniform(1, 10)     # Random float x, 1.0 <= x < 10.0
1.1800146073117523
>>> random.randint(1, 10)     # Integer from 1 to 10, endpoints included
7
>>> random.randrange(0, 101, 2) # Even integer from 0 to 100
26
>>> random.choice('abcdefghij') # Choose a random element
'c'
```

(continues on next page)

(continued from previous page)

```
>>> items = [1, 2, 3, 4, 5, 6, 7]
>>> random.shuffle(items)
>>> items
[7, 3, 2, 5, 6, 4, 1]

>>> random.sample([1, 2, 3, 4, 5], 3)  # Choose 3 elements
[4, 1, 5]
```

[Complementary-Multiply-with-Carry recipe](#) for a compatible alternative random number generator with a long period and comparatively simple update operations.

9.7 `itertools` — Functions creating iterators for efficient looping

New in version 2.3.

This module implements a number of *iterator* building blocks inspired by constructs from APL, Haskell, and SML. Each has been recast in a form suitable for Python.

The module standardizes a core set of fast, memory efficient tools that are useful by themselves or in combination. Together, they form an “iterator algebra” making it possible to construct specialized tools succinctly and efficiently in pure Python.

For instance, SML provides a tabulation tool: `tabulate(f)` which produces a sequence `f(0), f(1), ...`. The same effect can be achieved in Python by combining `imap()` and `count()` to form `imap(f, count())`.

These tools and their built-in counterparts also work well with the high-speed functions in the *operator* module. For example, the multiplication operator can be mapped across two vectors to form an efficient dot-product: `sum(imap(operator.mul, vector1, vector2))`.

Infinite Iterators:

| Iterator | Arguments | Results | Example |
|-----------------------|------------------|--|---|
| <code>count()</code> | start, [step] | start, start+step, start+2*step, ... | <code>count(10) --> 10 11 12 13 14 ...</code> |
| <code>cycle()</code> | p | p0, p1, ... plast, p0, p1, ... | <code>cycle('ABCD') --> A B C D A B C D ...</code> |
| <code>repeat()</code> | elem [,n] | elem, elem, elem, ... endlessly or up to n times | <code>repeat(10, 3) --> 10 10 10</code> |

Iterators terminating on the shortest input sequence:

| Iterator | Arguments | Results | Example |
|-----------------------------|-----------------------------|--|--|
| <code>chain()</code> | p, q, ... | p0, p1, ... plast, q0, q1, ... | <code>chain('ABC', 'DEF')</code> --> A B C D E F |
| <code>compress()</code> | data, selectors | (d[0] if s[0]), (d[1] if s[1]), ... | <code>compress('ABCDEF', [1,0,1,0,1,1])</code> --> A C E F |
| <code>dropwhile()</code> | pred, seq | seq[n], seq[n+1], starting when pred fails | <code>dropwhile(lambda x: x<5, [1,4,6,4,1])</code> --> 6 4 1 |
| <code>groupby()</code> | iterable[, key-func] | sub-iterators grouped by value of keyfunc(v) | |
| <code>ifilter()</code> | pred, seq | elements of seq where pred(elem) is true | <code>ifilter(lambda x: x%2, range(10))</code> --> 1 3 5 7 9 |
| <code>ifilterfalse()</code> | pred, seq | elements of seq where pred(elem) is false | <code>ifilterfalse(lambda x: x%2, range(10))</code> --> 0 2 4 6 8 |
| <code>islice()</code> | seq, [start,] stop [, step] | elements from seq[start:stop:step] | <code>islice('ABCDEFG', 2, None)</code> --> C D E F G |
| <code>imap()</code> | func, p, q, ... | func(p0, q0), func(p1, q1), ... | <code>imap(pow, (2,3,10), (5,2,3))</code> --> 32 9 1000 |
| <code>starmap()</code> | func, seq | func(*seq[0]), func(*seq[1]), ... | <code>starmap(pow, [(2,5), (3,2), (10,3)])</code> --> 32 9 1000 |
| <code>tee()</code> | it, n | it1, it2, ... itn splits one iterator into n | |
| <code>takewhile()</code> | pred, seq | seq[0], seq[1], until pred fails | <code>takewhile(lambda x: x<5, [1,4,6,4,1])</code> --> 1 4 |
| <code>izip()</code> | p, q, ... | (p[0], q[0]), (p[1], q[1]), ... | <code>izip('ABCD', 'xy')</code> --> Ax By |
| <code>izip_longest()</code> | p, q, ... | (p[0], q[0]), (p[1], q[1]), ... | <code>izip_longest('ABCD', 'xy', fillvalue='-')</code> --> Ax By C- D- |

Combinatoric generators:

| Iterator | Arguments | Results |
|---|----------------------|---|
| <code>product()</code> | p, q, ... [repeat=1] | cartesian product, equivalent to a nested for-loop |
| <code>permutations()</code> | p[, r] | r-length tuples, all possible orderings, no repeated elements |
| <code>combinations()</code> | p, r | r-length tuples, in sorted order, no repeated elements |
| <code>combinations_with_replacement()</code> | p, r | r-length tuples, in sorted order, with repeated elements |
| <code>product('ABCD', repeat=2)</code> | | AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD |
| <code>permutations('ABCD', 2)</code> | | AB AC AD BA BC BD CA CB CD DA DB DC |
| <code>combinations('ABCD', 2)</code> | | AB AC AD BC BD CD |
| <code>combinations_with_replacement('ABCD', 2)</code> | | AA AB AC AD BB BC BD CC CD DD |

9.7.1 Itertool functions

The following module functions all construct and return iterators. Some provide streams of infinite length, so they should only be accessed by functions or loops that truncate the stream.

`itertools.chain(*iterables)`

Make an iterator that returns elements from the first iterable until it is exhausted, then proceeds to the next iterable, until all of the iterables are exhausted. Used for treating consecutive sequences as a single sequence. Roughly equivalent to:

```
def chain(*iterables):
    # chain('ABC', 'DEF') --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

classmethod `chain.from_iterable(iterable)`

Alternate constructor for `chain()`. Gets chained inputs from a single iterable argument that is evaluated lazily. Roughly equivalent to:

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

New in version 2.6.

`itertools.combinations(iterable, r)`

Return *r* length subsequences of elements from the input *iterable*.

Combinations are emitted in lexicographic sort order. So, if the input *iterable* is sorted, the combination tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeat values in each combination.

Roughly equivalent to:

```
def combinations(iterable, r):
    # combinations('ABCD', 2) --> AB AC AD BC BD CD
    # combinations(range(4), 3) --> 012 013 023 123
    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = range(r)
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
        else:
            return
        indices[i] += 1
        for j in range(i+1, r):
            indices[j] = indices[j-1] + 1
        yield tuple(pool[i] for i in indices)
```

The code for `combinations()` can be also expressed as a subsequence of `permutations()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```
def combinations(iterable, r):
    pool = tuple(iterable)
```

(continues on next page)

(continued from previous page)

```
n = len(pool)
for indices in permutations(range(n), r):
    if sorted(indices) == list(indices):
        yield tuple(pool[i] for i in indices)
```

The number of items returned is $n! / r! / (n-r)!$ when $0 \leq r \leq n$ or zero when $r > n$.

New in version 2.6.

`itertools.combinations_with_replacement(iterable, r)`

Return r length subsequences of elements from the input *iterable* allowing individual elements to be repeated more than once.

Combinations are emitted in lexicographic sort order. So, if the input *iterable* is sorted, the combination tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, the generated combinations will also be unique.

Roughly equivalent to:

```
def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) --> AA AB AC BB BC CC
    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)
```

The code for `combinations_with_replacement()` can be also expressed as a subsequence of `product()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```
def combinations_with_replacement(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in product(range(n), repeat=r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)
```

The number of items returned is $(n+r-1)! / r! / (n-1)!$ when $n > 0$.

New in version 2.7.

`itertools.compress(data, selectors)`

Make an iterator that filters elements from *data* returning only those that have a corresponding element in *selectors* that evaluates to True. Stops when either the *data* or *selectors* iterables has been exhausted. Roughly equivalent to:

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F
    return (d for d, s in izip(data, selectors) if s)
```

New in version 2.7.

`itertools.count` (*start=0, step=1*)

Make an iterator that returns evenly spaced values starting with *n*. Often used as an argument to `imap()` to generate consecutive data points. Also, used with `izip()` to add sequence numbers. Equivalent to:

```
def count(start=0, step=1):
    # count(10) --> 10 11 12 13 14 ...
    # count(2.5, 0.5) -> 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

When counting with floating point numbers, better accuracy can sometimes be achieved by substituting multiplicative code such as: `(start + step * i for i in count())`.

Changed in version 2.7: added *step* argument and allowed non-integer arguments.

`itertools.cycle` (*iterable*)

Make an iterator returning elements from the iterable and saving a copy of each. When the iterable is exhausted, return elements from the saved copy. Repeats indefinitely. Roughly equivalent to:

```
def cycle(iterable):
    # cycle('ABCD') --> A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
    while saved:
        for element in saved:
            yield element
```

Note, this member of the toolkit may require significant auxiliary storage (depending on the length of the iterable).

`itertools.dropwhile` (*predicate, iterable*)

Make an iterator that drops elements from the iterable as long as the predicate is true; afterwards, returns every element. Note, the iterator does not produce *any* output until the predicate first becomes false, so it may have a lengthy start-up time. Roughly equivalent to:

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1
    iterable = iter(iterable)
    for x in iterable:
        if not predicate(x):
            yield x
            break
    for x in iterable:
        yield x
```

`itertools.groupby` (*iterable*[, *key*])

Make an iterator that returns consecutive keys and groups from the *iterable*. The *key* is a function computing a key value for each element. If not specified or is `None`, *key* defaults to an identity function and returns the element unchanged. Generally, the iterable needs to already be sorted on the same key function.

The operation of `groupby()` is similar to the `uniq` filter in Unix. It generates a break or new group every time the value of the key function changes (which is why it is usually necessary to have sorted the data using the same key function). That behavior differs from SQL's GROUP BY which aggregates common elements regardless of their input order.

The returned group is itself an iterator that shares the underlying iterable with `groupby()`. Because the source is shared, when the `groupby()` object is advanced, the previous group is no longer visible. So, if that data is needed later, it should be stored as a list:

```
groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)
```

`groupby()` is roughly equivalent to:

```
class groupby(object):
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --> A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] --> AAAA BBB CC D
    def __init__(self, iterable, key=None):
        if key is None:
            key = lambda x: x
        self.keyfunc = key
        self.it = iter(iterable)
        self.tgtkey = self.currkey = self.currvalue = object()
    def __iter__(self):
        return self
    def next(self):
        while self.currkey == self.tgtkey:
            self.currvalue = next(self.it)      # Exit on StopIteration
            self.currkey = self.keyfunc(self.currvalue)
        self.tgtkey = self.currkey
        return (self.currkey, self._grouper(self.tgtkey))
    def _grouper(self, tgtkey):
        while self.currkey == tgtkey:
            yield self.currvalue
            self.currvalue = next(self.it)      # Exit on StopIteration
            self.currkey = self.keyfunc(self.currvalue)
```

New in version 2.4.

`itertools.ifilter(predicate, iterable)`

Make an iterator that filters elements from `iterable` returning only those for which the predicate is `True`. If `predicate` is `None`, return the items that are true. Roughly equivalent to:

```
def ifilter(predicate, iterable):
    # ifilter(lambda x: x%2, range(10)) --> 1 3 5 7 9
    if predicate is None:
        predicate = bool
    for x in iterable:
        if predicate(x):
            yield x
```

`itertools.ifilterfalse(predicate, iterable)`

Make an iterator that filters elements from `iterable` returning only those for which the predicate is `False`. If `predicate` is `None`, return the items that are false. Roughly equivalent to:

```
def ifilterfalse(predicate, iterable):
    # ifilterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x
```

`itertools.imap(function, *iterables)`

Make an iterator that computes the function using arguments from each of the iterables. If *function* is set to `None`, then `imap()` returns the arguments as a tuple. Like `map()` but stops when the shortest iterable is exhausted instead of filling in `None` for shorter iterables. The reason for the difference is that infinite iterator arguments are typically an error for `map()` (because the output is fully evaluated) but represent a common and useful way of supplying arguments to `imap()`. Roughly equivalent to:

```
def imap(function, *iterables):
    # imap(pow, (2,3,10), (5,2,3)) --> 32 9 1000
    iterables = map(iter, iterables)
    while True:
        args = [next(it) for it in iterables]
        if function is None:
            yield tuple(args)
        else:
            yield function(*args)
```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

Make an iterator that returns selected elements from the iterable. If *start* is non-zero, then elements from the iterable are skipped until *start* is reached. Afterward, elements are returned consecutively unless *step* is set higher than one which results in items being skipped. If *stop* is `None`, then iteration continues until the iterator is exhausted, if at all; otherwise, it stops at the specified position. Unlike regular slicing, `islice()` does not support negative values for *start*, *stop*, or *step*. Can be used to extract related fields from data where the internal structure has been flattened (for example, a multi-line report may list a name field on every third line). Roughly equivalent to:

```
def islice(iterable, *args):
    # islice('ABCDEFGH', 2) --> A B
    # islice('ABCDEFGH', 2, 4) --> C D
    # islice('ABCDEFGH', 2, None) --> C D E F G
    # islice('ABCDEFGH', 0, None, 2) --> A C E G
    s = slice(*args)
    start, stop, step = s.start or 0, s.stop or sys.maxint, s.step or 1
    it = iter(xrange(start, stop, step))
    try:
        nexti = next(it)
    except StopIteration:
        # Consume *iterable* up to the *start* position.
        for i, element in izip(xrange(start), iterable):
            pass
        return
    try:
        for i, element in enumerate(iterable):
            if i == nexti:
                yield element
                nexti = next(it)
    except StopIteration:
        # Consume to *stop*.
```

(continues on next page)

(continued from previous page)

```
for i, element in izip(xrange(i + 1, stop), iterable):
    pass
```

If *start* is *None*, then iteration starts at zero. If *step* is *None*, then the step defaults to one.

Changed in version 2.5: accept *None* values for default *start* and *step*.

`itertools.izip(*iterables)`

Make an iterator that aggregates elements from each of the iterables. Like `zip()` except that it returns an iterator instead of a list. Used for lock-step iteration over several iterables at a time. Roughly equivalent to:

```
def izip(*iterables):
    # izip('ABCD', 'xy') --> Ax By
    iterators = map(iter, iterables)
    while iterators:
        yield tuple(map(next, iterators))
```

Changed in version 2.4: When no iterables are specified, returns a zero length iterator instead of raising a `TypeError` exception.

The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into *n*-length groups using `izip(*[iter(s)]*n)`.

`izip()` should only be used with unequal length inputs when you don't care about trailing, unmatched values from the longer iterables. If those values are important, use `izip_longest()` instead.

`itertools.izip_longest(*iterables[, fillvalue])`

Make an iterator that aggregates elements from each of the iterables. If the iterables are of uneven length, missing values are filled-in with *fillvalue*. Iteration continues until the longest iterable is exhausted. Roughly equivalent to:

```
class ZipExhausted(Exception):
    pass

def izip_longest(*args, **kwargs):
    # izip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C- D-
    fillvalue = kwargs.get('fillvalue')
    counter = [len(args) - 1]
    def sentinel():
        if not counter[0]:
            raise ZipExhausted
        counter[0] -= 1
        yield fillvalue
    fillers = repeat(fillvalue)
    iterators = [chain(it, sentinel(), fillers) for it in args]
    try:
        while iterators:
            yield tuple(map(next, iterators))
    except ZipExhausted:
        pass
```

If one of the iterables is potentially infinite, then the `izip_longest()` function should be wrapped with something that limits the number of calls (for example `islice()` or `takewhile()`). If not specified, *fillvalue* defaults to *None*.

New in version 2.6.

`itertools.permutations(iterable[, r])`

Return successive *r* length permutations of elements in the *iterable*.

If *r* is not specified or is `None`, then *r* defaults to the length of the *iterable* and all possible full-length permutations are generated.

Permutations are emitted in lexicographic sort order. So, if the input *iterable* is sorted, the permutation tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeat values in each permutation.

Roughly equivalent to:

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) --> AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) --> 012 021 102 120 201 210
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return
    indices = range(n)
    cycles = range(n, n-r, -1)
    yield tuple(pool[i] for i in indices[:r])
    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return
```

The code for `permutations()` can be also expressed as a subsequence of `product()`, filtered to exclude entries with repeated elements (those from the same position in the input pool):

```
def permutations(iterable, r=None):
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    for indices in product(range(n), repeat=r):
        if len(set(indices)) == r:
            yield tuple(pool[i] for i in indices)
```

The number of items returned is $n! / (n-r)!$ when $0 \leq r \leq n$ or zero when $r > n$.

New in version 2.6.

`itertools.product(*iterables[, repeat])`
 Cartesian product of input iterables.

Roughly equivalent to nested for-loops in a generator expression. For example, `product(A, B)` returns the same as `((x,y) for x in A for y in B)`.

The nested loops cycle like an odometer with the rightmost element advancing on every iteration. This pattern creates a lexicographic ordering so that if the input's iterables are sorted, the product tuples are emitted in sorted order.

To compute the product of an iterable with itself, specify the number of repetitions with the optional *repeat* keyword argument. For example, `product(A, repeat=4)` means the same as `product(A, A, A, A)`.

This function is roughly equivalent to the following code, except that the actual implementation does not build up intermediate results in memory:

```
def product(*args, **kwargs):
    # product('ABCD', 'xy') --> Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) --> 000 001 010 011 100 101 110 111
    pools = map(tuple, args) * kwargs.get('repeat', 1)
    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]
    for prod in result:
        yield tuple(prod)
```

New in version 2.6.

`itertools.repeat(object[, times])`

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified. Used as argument to `imap()` for invariant function parameters. Also used with `izip()` to create constant fields in a tuple record. Roughly equivalent to:

```
def repeat(object, times=None):
    # repeat(10, 3) --> 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in xrange(times):
            yield object
```

A common use for *repeat* is to supply a stream of constant values to *imap* or *zip*:

```
>>> list(imap(pow, xrange(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

`itertools.starmap(function, iterable)`

Make an iterator that computes the function using arguments obtained from the iterable. Used instead of `imap()` when argument parameters are already grouped in tuples from a single iterable (the data has been “pre-zipped”). The difference between `imap()` and `starmap()` parallels the distinction between `function(a,b)` and `function(*c)`. Roughly equivalent to:

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000
    for args in iterable:
        yield function(*args)
```

Changed in version 2.6: Previously, `starmap()` required the function arguments to be tuples. Now, any iterable is allowed.

`itertools.takewhile(predicate, iterable)`

Make an iterator that returns elements from the iterable as long as the predicate is true. Roughly equivalent to:

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4
    for x in iterable:
        if predicate(x):
```

(continues on next page)

(continued from previous page)

```

        yield x
    else:
        break

```

`itertools.tee(iterable[, n=2])`

Return *n* independent iterators from a single iterable. Roughly equivalent to:

```

def tee(iterable, n=2):
    it = iter(iterable)
    deques = [collections.deque() for i in range(n)]
    def gen(mydeque):
        while True:
            if not mydeque:          # when the local deque is empty
                newval = next(it)    # fetch a new value and
                for d in deques:    # load it to all the deques
                    d.append(newval)
            yield mydeque.popleft()
    return tuple(gen(d) for d in deques)

```

Once `tee()` has made a split, the original *iterable* should not be used anywhere else; otherwise, the *iterable* could get advanced without the tee objects being informed.

This *itertools* may require significant auxiliary storage (depending on how much temporary data needs to be stored). In general, if one iterator uses most or all of the data before another iterator starts, it is faster to use `list()` instead of `tee()`.

New in version 2.4.

9.7.2 Recipes

This section shows recipes for creating an extended toolset using the existing *itertools* as building blocks.

The extended tools offer the same high performance as the underlying toolset. The superior memory performance is kept by processing elements one at a time rather than bringing the whole iterable into memory all at once. Code volume is kept small by linking the tools together in a functional style which helps eliminate temporary variables. High speed is retained by preferring “vectorized” building blocks over the use of for-loops and *generators* which incur interpreter overhead.

```

def take(n, iterable):
    "Return first n items of the iterable as a list"
    return list(islice(iterable, n))

def tabulate(function, start=0):
    "Return function(0), function(1), ..."
    return imap(function, count(start))

def consume(iterator, n=None):
    "Advance the iterator n-steps ahead. If n is None, consume entirely."
    # Use functions that consume iterators at C speed.
    if n is None:
        # feed the entire iterator into a zero-length deque
        collections.deque(iterator, maxlen=0)
    else:
        # advance to the empty slice starting at position n
        next(islice(iterator, n, n), None)

def nth(iterable, n, default=None):

```

(continues on next page)

(continued from previous page)

```

    "Returns the nth item or a default value"
    return next(islice(iterable, n, None), default)

def all_equal(iterable):
    "Returns True if all the elements are equal to each other"
    g = groupby(iterable)
    return next(g, True) and not next(g, False)

    return imap(next, imap(itemgetter(1), groupby(iterable, key)))

def iter_except(func, exception, first=None):
    """ Call a function repeatedly until an exception is raised.

    Converts a call-until-exception interface to an iterator interface.
    Like __builtin__.iter(func, sentinel) but uses an exception instead
    of a sentinel to end the loop.

    Examples:
    bsddbiter = iter_except(db.next, bsddb.error, db.first)
    heapiter = iter_except(functools.partial(heapop, h), IndexError)
    dictiter = iter_except(d.popitem, KeyError)
    dequeiter = iter_except(d.popleft, IndexError)
    queueiter = iter_except(q.get_nowait, Queue.Empty)
    setiter = iter_except(s.pop, KeyError)

    """
    try:
        if first is not None:
            yield first()
        while 1:
            yield func()
    except exception:

```

(continues on next page)

(continued from previous page)

```

    pass

def random_product(*args, **kwds):
    "Random selection from itertools.product(*args, **kwds)"
    pools = map(tuple, args) * kwds.get('repeat', 1)
    return tuple(random.choice(pool) for pool in pools)

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(xrange(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Random selection from itertools.combinations_with_replacement(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.randrange(n) for i in xrange(r))
    return tuple(pool[i] for i in indices)

def tee_lookahead(t, i):
    """Inspect the i-th upcoming value from a tee object
       while leaving the tee object at its current position.

       Raise an IndexError if the underlying iterator doesn't
       have enough values.

    """
    for value in islice(t.__copy__(), i, None):
        return value
    raise IndexError(i)

```

Note, many of the above recipes can be optimized by replacing global lookups with local variables defined as default values. For example, the *dotproduct* recipe can be written as:

```

def dotproduct(vec1, vec2, sum=sum, imap=imap, mul=operator.mul):
    return sum(imap(mul, vec1, vec2))

```

9.8 functools — Higher-order functions and operations on callable objects

New in version 2.5.

Source code: [Lib/functools.py](#)

The `functools` module is for higher-order functions: functions that act on or return other functions. In general, any callable object can be treated as a function for the purposes of this module.

The `functools` module defines the following functions:

`functools.cmp_to_key(func)`

Transform an old-style comparison function to a *key function*. Used with tools that accept key functions (such as `sorted()`, `min()`, `max()`, `heapq.nlargest()`, `heapq.nsmallest()`, `itertools.groupby()`). This function is primarily used as a transition tool for programs being converted to Python 3 where comparison functions are no longer supported.

A comparison function is any callable that accept two arguments, compares them, and returns a negative number for less-than, zero for equality, or a positive number for greater-than. A key function is a callable that accepts one argument and returns another value to be used as the sort key.

Example:

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) # locale-aware sort order
```

For sorting examples and a brief sorting tutorial, see [sortinghowto](#).

New in version 2.7.

`functools.total_ordering(cls)`

Given a class defining one or more rich comparison ordering methods, this class decorator supplies the rest. This simplifies the effort involved in specifying all of the possible rich comparison operations:

The class must define one of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. In addition, the class should supply an `__eq__()` method.

For example:

```
@total_ordering
class Student:
    def __eq__(self, other):
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

New in version 2.7.

`functools.reduce(function, iterable[, initializer])`

This is the same function as `reduce()`. It is made available in this module to allow writing code more forward-compatible with Python 3.

New in version 2.6.

`functools.partial(func[, *args][, **keywords])`

Return a new *partial object* which when called will behave like `func` called with the positional arguments `args` and keyword arguments `keywords`. If more arguments are supplied to the call, they are appended to `args`. If additional keyword arguments are supplied, they extend and override `keywords`. Roughly equivalent to:

```
def partial(func, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = keywords.copy()
        newkeywords.update(fkeywords)
        return func(*(args + fargs), **newkeywords)
    newfunc.func = func
```

(continues on next page)

(continued from previous page)

```

newfunc.args = args
newfunc.keywords = keywords
return newfunc

```

The `partial()` is used for partial function application which “freezes” some portion of a function’s arguments and/or keywords resulting in a new object with a simplified signature. For example, `partial()` can be used to create a callable that behaves like the `int()` function where the `base` argument defaults to two:

```

>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18

```

`functools.update_wrapper(wrapper, wrapped[, assigned][, updated])`

Update a `wrapper` function to look like the `wrapped` function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function’s `__name__`, `__module__` and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function’s `__dict__`, i.e. the instance dictionary).

The main intended use for this function is in `decorator` functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

`functools.wraps(wrapped[, assigned][, updated])`

This is a convenience function for invoking `update_wrapper()` as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```

>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwds):
...         print 'Calling decorated function'
...         return f(*args, **kwds)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print 'Called example function'
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'

```

Without the use of this decorator factory, the name of the example function would have been `'wrapper'`, and the docstring of the original `example()` would have been lost.

9.8.1 `partial` Objects

`partial` objects are callable objects created by `partial()`. They have three read-only attributes:

`partial.func`

A callable object or function. Calls to the `partial` object will be forwarded to `func` with new arguments and keywords.

`partial.args`

The leftmost positional arguments that will be prepended to the positional arguments provided to a `partial` object call.

`partial.keywords`

The keyword arguments that will be supplied when the `partial` object is called.

`partial` objects are like `function` objects in that they are callable, weak referencable, and can have attributes. There are some important differences. For instance, the `__name__` and `__doc__` attributes are not created automatically. Also, `partial` objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

9.9 `operator` — Standard operators as functions

The `operator` module exports a set of efficient functions corresponding to the intrinsic operators of Python. For example, `operator.add(x, y)` is equivalent to the expression `x+y`. The function names are those used for special class methods; variants without leading and trailing `__` are also provided for convenience.

The functions fall into categories that perform object comparisons, logical operations, mathematical operations, sequence operations, and abstract type tests.

The object comparison functions are useful for all objects, and are named after the rich comparison operators they support:

```
operator.lt(a, b)
operator.le(a, b)
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator.__lt__(a, b)
operator.__le__(a, b)
operator.__eq__(a, b)
operator.__ne__(a, b)
operator.__ge__(a, b)
operator.__gt__(a, b)
```

Perform “rich comparisons” between `a` and `b`. Specifically, `lt(a, b)` is equivalent to `a < b`, `le(a, b)` is equivalent to `a <= b`, `eq(a, b)` is equivalent to `a == b`, `ne(a, b)` is equivalent to `a != b`, `gt(a, b)` is equivalent to `a > b` and `ge(a, b)` is equivalent to `a >= b`. Note that unlike the built-in `cmp()`, these functions can return any value, which may or may not be interpretable as a Boolean value. See comparisons for more information about rich comparisons.

New in version 2.2.

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations:

```
operator.not_(obj)
```

`operator.__not__(obj)`

Return the outcome of `not obj`. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__nonzero__()` and `__len__()` methods.)

`operator.truth(obj)`

Return `True` if `obj` is true, and `False` otherwise. This is equivalent to using the `bool` constructor.

`operator.is_(a, b)`

Return `a is b`. Tests object identity.

New in version 2.3.

`operator.is_not(a, b)`

Return `a is not b`. Tests object identity.

New in version 2.3.

The mathematical and bitwise operations are the most numerous:

`operator.abs(obj)`

`operator.__abs__(obj)`

Return the absolute value of `obj`.

`operator.add(a, b)`

`operator.__add__(a, b)`

Return `a + b`, for `a` and `b` numbers.

`operator.and_(a, b)`

`operator.__and__(a, b)`

Return the bitwise and of `a` and `b`.

`operator.div(a, b)`

`operator.__div__(a, b)`

Return `a / b` when `__future__.division` is not in effect. This is also known as “classic” division.

`operator.floordiv(a, b)`

`operator.__floordiv__(a, b)`

Return `a // b`.

New in version 2.2.

`operator.index(a)`

`operator.__index__(a)`

Return `a` converted to an integer. Equivalent to `a.__index__()`.

New in version 2.5.

`operator.inv(obj)`

`operator.invert(obj)`

`operator.__inv__(obj)`

`operator.__invert__(obj)`

Return the bitwise inverse of the number `obj`. This is equivalent to `~obj`.

New in version 2.0: The names `invert()` and `__invert__()`.

`operator.lshift(a, b)`

`operator.__lshift__(a, b)`

Return `a` shifted left by `b`.

`operator.mod(a, b)`

`operator.__mod__(a, b)`

Return `a % b`.

```

operator.mul(a, b)
operator.__mul__(a, b)
    Return a * b, for a and b numbers.

operator.neg(obj)
operator.__neg__(obj)
    Return obj negated (-obj).

operator.or_(a, b)
operator.__or__(a, b)
    Return the bitwise or of a and b.

operator.pos(obj)
operator.__pos__(obj)
    Return obj positive (+obj).

operator.pow(a, b)
operator.__pow__(a, b)
    Return a ** b, for a and b numbers.

    New in version 2.3.

operator.rshift(a, b)
operator.__rshift__(a, b)
    Return a shifted right by b.

operator.sub(a, b)
operator.__sub__(a, b)
    Return a - b.

operator.truediv(a, b)
operator.__truediv__(a, b)
    Return a / b when __future__.division is in effect. This is also known as “true” division.

    New in version 2.2.

operator.xor(a, b)
operator.__xor__(a, b)
    Return the bitwise exclusive or of a and b.

```

Operations which work with sequences (some of them with mappings too) include:

```

operator.concat(a, b)
operator.__concat__(a, b)
    Return a + b for a and b sequences.

operator.contains(a, b)
operator.__contains__(a, b)
    Return the outcome of the test b in a. Note the reversed operands.

    New in version 2.0: The name __contains__().

operator.countOf(a, b)
    Return the number of occurrences of b in a.

operator.delitem(a, b)
operator.__delitem__(a, b)
    Remove the value of a at index b.

operator.delslice(a, b, c)
operator.__delslice__(a, b, c)
    Delete the slice of a from index b to index c-1.

```

Deprecated since version 2.6: This function is removed in Python 3.x. Use `delitem()` with a slice index.

```
operator.getitem(a, b)
operator.__getitem__(a, b)
    Return the value of a at index b.
```

```
operator.getslice(a, b, c)
operator.__getslice__(a, b, c)
    Return the slice of a from index b to index c-1.
```

Deprecated since version 2.6: This function is removed in Python 3.x. Use `getitem()` with a slice index.

```
operator.indexof(a, b)
    Return the index of the first of occurrence of b in a.
```

```
operator.repeat(a, b)
operator.__repeat__(a, b)
    Deprecated since version 2.7: Use __mul__() instead.

    Return a * b where a is a sequence and b is an integer.
```

```
operator.sequenceIncludes(...)
    Deprecated since version 2.0: Use contains() instead.

    Alias for contains().
```

```
operator.setitem(a, b, c)
operator.__setitem__(a, b, c)
    Set the value of a at index b to c.
```

```
operator.setslice(a, b, c, v)
operator.__setslice__(a, b, c, v)
    Set the slice of a from index b to index c-1 to the sequence v.
```

Deprecated since version 2.6: This function is removed in Python 3.x. Use `setitem()` with a slice index.

Example use of operator functions:

```
>>> # Elementwise multiplication
>>> map(mul, [0, 1, 2, 3], [10, 20, 30, 40])
[0, 20, 60, 120]

>>> # Dot product
>>> sum(map(mul, [0, 1, 2, 3], [10, 20, 30, 40]))
200
```

Many operations have an “in-place” version. The following functions provide a more primitive access to in-place operators than the usual syntax does; for example, the *statement* `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

```
operator.iadd(a, b)
operator.__iadd__(a, b)
    a = iadd(a, b) is equivalent to a += b.
```

New in version 2.5.

```
operator.iand(a, b)
operator.__iand__(a, b)
    a = iand(a, b) is equivalent to a &= b.
```

New in version 2.5.

`operator.iconcat(a, b)`
`operator.__iconcat__(a, b)`
`a = iconcat(a, b)` is equivalent to `a += b` for *a* and *b* sequences.

New in version 2.5.

`operator.idiv(a, b)`
`operator.__idiv__(a, b)`
`a = idiv(a, b)` is equivalent to `a /= b` when `__future__.division` is not in effect.

New in version 2.5.

`operator.ifloordiv(a, b)`
`operator.__ifloordiv__(a, b)`
`a = ifloordiv(a, b)` is equivalent to `a //= b`.

New in version 2.5.

`operator.ilshift(a, b)`
`operator.__ilshift__(a, b)`
`a = ilshift(a, b)` is equivalent to `a <<= b`.

New in version 2.5.

`operator.imod(a, b)`
`operator.__imod__(a, b)`
`a = imod(a, b)` is equivalent to `a %= b`.

New in version 2.5.

`operator.imul(a, b)`
`operator.__imul__(a, b)`
`a = imul(a, b)` is equivalent to `a *= b`.

New in version 2.5.

`operator.ior(a, b)`
`operator.__ior__(a, b)`
`a = ior(a, b)` is equivalent to `a |= b`.

New in version 2.5.

`operator.ipow(a, b)`
`operator.__ipow__(a, b)`
`a = ipow(a, b)` is equivalent to `a **= b`.

New in version 2.5.

`operator.irepeat(a, b)`
`operator.__irepeat__(a, b)`
 Deprecated since version 2.7: Use `__imul__()` instead.
`a = irepeat(a, b)` is equivalent to `a *= b` where *a* is a sequence and *b* is an integer.

New in version 2.5.

`operator.irshift(a, b)`
`operator.__irshift__(a, b)`
`a = irshift(a, b)` is equivalent to `a >>= b`.

New in version 2.5.

`operator.isub(a, b)`

`operator.__isub__(a, b)`
`a = isub(a, b)` is equivalent to `a -= b`.

New in version 2.5.

`operator.itruediv(a, b)`
`operator.__itruediv__(a, b)`
`a = itruediv(a, b)` is equivalent to `a /= b` when `__future__.division` is in effect.

New in version 2.5.

`operator.ixor(a, b)`
`operator.__ixor__(a, b)`
`a = ixor(a, b)` is equivalent to `a ^= b`.

New in version 2.5.

The `operator` module also defines a few predicates to test the type of objects; however, these are not all reliable. It is preferable to test abstract base classes instead (see `collections` and `numbers` for details).

`operator.isCallable(obj)`
Deprecated since version 2.0: Use `isinstance(x, collections.Callable)` instead.

Returns true if the object `obj` can be called like a function, otherwise it returns false. True is returned for functions, bound and unbound methods, class objects, and instance objects which support the `__call__()` method.

`operator.isMappingType(obj)`
Deprecated since version 2.7: Use `isinstance(x, collections.Mapping)` instead.

Returns true if the object `obj` supports the mapping interface. This is true for dictionaries and all instance objects defining `__getitem__()`.

`operator.isNumberType(obj)`
Deprecated since version 2.7: Use `isinstance(x, numbers.Number)` instead.

Returns true if the object `obj` represents a number. This is true for all numeric types implemented in C.

`operator.isSequenceType(obj)`
Deprecated since version 2.7: Use `isinstance(x, collections.Sequence)` instead.

Returns true if the object `obj` supports the sequence protocol. This returns true for all objects which define sequence methods in C, and for all instance objects defining `__getitem__()`.

The `operator` module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for `map()`, `sorted()`, `itertools.groupby()`, or other functions that expect a function argument.

`operator.attrgetter(attr)`
`operator.attrgetter(*attrs)`

Return a callable object that fetches `attr` from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example:

- After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.
- After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.
- After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns `(b.name.first, b.name.last)`.

Equivalent to:

```
def attrgetter(*items):  
    if len(items) == 1:  
        item = items[0]
```

(continues on next page)

(continued from previous page)

```

    attr = items[0]
    def g(obj):
        return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj

```

New in version 2.4.

Changed in version 2.5: Added support for multiple attributes.

Changed in version 2.6: Added support for dotted attributes.

`operator.itemgetter(item)`

`operator.itemgetter(*items)`

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method. If multiple items are specified, returns a tuple of lookup values. For example:

- After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.
- After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

Equivalent to:

```

def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g

```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any hashable value. Lists, tuples, and strings accept an index or a slice:

```

>>> itemgetter(1)('ABCDEFGH')
'B'
>>> itemgetter(1,3,5)('ABCDEFGH')
('B', 'D', 'F')
>>> itemgetter(slice(2,None))('ABCDEFGH')
'CDEFG'

```

New in version 2.4.

Changed in version 2.5: Added support for multiple item extraction.

Example of using `itemgetter()` to retrieve specific fields from a tuple record:

```

>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> map(getcount, inventory)

```

(continues on next page)

(continued from previous page)

```
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

`operator.methodcaller` (*name*[, *args...*])

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example:

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
- After `f = methodcaller('name', 'foo', bar=1)`, the call `f(b)` returns `b.name('foo', bar=1)`.

Equivalent to:

```
def methodcaller(name, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

New in version 2.6.

9.9.1 Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the `operator` module.

| Operation | Syntax | Function |
|-----------------------|---------------------------|---|
| Addition | <code>a + b</code> | <code>add(a, b)</code> |
| Concatenation | <code>seq1 + seq2</code> | <code>concat(seq1, seq2)</code> |
| Containment Test | <code>obj in seq</code> | <code>contains(seq, obj)</code> |
| Division | <code>a / b</code> | <code>div(a, b)</code> (without <code>__future__.division</code>) |
| Division | <code>a / b</code> | <code>truediv(a, b)</code> (with <code>__future__.division</code>) |
| Division | <code>a // b</code> | <code>floordiv(a, b)</code> |
| Bitwise And | <code>a & b</code> | <code>and_(a, b)</code> |
| Bitwise Exclusive Or | <code>a ^ b</code> | <code>xor(a, b)</code> |
| Bitwise Inversion | <code>~ a</code> | <code>invert(a)</code> |
| Bitwise Or | <code>a b</code> | <code>or_(a, b)</code> |
| Exponentiation | <code>a ** b</code> | <code>pow(a, b)</code> |
| Identity | <code>a is b</code> | <code>is_(a, b)</code> |
| Identity | <code>a is not b</code> | <code>is_not(a, b)</code> |
| Indexed Assignment | <code>obj[k] = v</code> | <code>setitem(obj, k, v)</code> |
| Indexed Deletion | <code>del obj[k]</code> | <code>delitem(obj, k)</code> |
| Indexing | <code>obj[k]</code> | <code>getitem(obj, k)</code> |
| Left Shift | <code>a << b</code> | <code>lshift(a, b)</code> |
| Modulo | <code>a % b</code> | <code>mod(a, b)</code> |
| Multiplication | <code>a * b</code> | <code>mul(a, b)</code> |
| Negation (Arithmetic) | <code>- a</code> | <code>neg(a)</code> |
| Negation (Logical) | <code>not a</code> | <code>not_(a)</code> |
| Positive | <code>+ a</code> | <code>pos(a)</code> |
| Right Shift | <code>a >> b</code> | <code>rshift(a, b)</code> |
| Sequence Repetition | <code>seq * i</code> | <code>repeat(seq, i)</code> |

Continued on next page

Table 1 – continued from previous page

| Operation | Syntax | Function |
|-------------------|--------------------------------|--|
| Slice Assignment | <code>seq[i:j] = values</code> | <code>setitem(seq, slice(i, j), values)</code> |
| Slice Deletion | <code>del seq[i:j]</code> | <code>delitem(seq, slice(i, j))</code> |
| Slicing | <code>seq[i:j]</code> | <code>getitem(seq, slice(i, j))</code> |
| String Formatting | <code>s % obj</code> | <code>mod(s, obj)</code> |
| Subtraction | <code>a - b</code> | <code>sub(a, b)</code> |
| Truth Test | <code>obj</code> | <code>truth(obj)</code> |
| Ordering | <code>a < b</code> | <code>lt(a, b)</code> |
| Ordering | <code>a <= b</code> | <code>le(a, b)</code> |
| Equality | <code>a == b</code> | <code>eq(a, b)</code> |
| Difference | <code>a != b</code> | <code>ne(a, b)</code> |
| Ordering | <code>a >= b</code> | <code>ge(a, b)</code> |
| Ordering | <code>a > b</code> | <code>gt(a, b)</code> |

FILE AND DIRECTORY ACCESS

The modules described in this chapter deal with disk files and directories. For example, there are modules for reading the properties of files, manipulating paths in a portable way, and creating temporary files. The full list of modules in this chapter is:

10.1 `os.path` — Common pathname manipulations

This module implements some useful functions on pathnames. To read or write files see `open()`, and for accessing the filesystem see the `os` module.

Note: On Windows, many of these functions do not properly support UNC pathnames. `splitunc()` and `ismount()` do handle them correctly.

Unlike a unix shell, Python does not do any *automatic* path expansions. Functions such as `expanduser()` and `expandvars()` can be invoked explicitly when an application desires shell-like path expansion. (See also the `glob` module.)

Note: Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The `os.path` module is always the path module suitable for the operating system Python is running on, and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface:

- `posixpath` for UNIX-style paths
 - `ntpath` for Windows paths
 - `macpath` for old-style MacOS paths
 - `os2emxpath` for OS/2 EMX paths
-

`os.path.abspath(path)`

Return a normalized absolutized version of the pathname `path`. On most platforms, this is equivalent to calling the function `normpath()` as follows: `normpath(join(os.getcwd(), path))`.

New in version 1.5.2.

`os.path.basename(path)`

Return the base name of pathname `path`. This is the second element of the pair returned by passing `path` to the function `split()`. Note that the result of this function is different from the Unix **basename** program; where **basename** for `'/foo/bar/'` returns `'bar'`, the `basename()` function returns an empty string `('')`.

`os.path.commonprefix(list)`

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string (''). Note that this may return invalid paths because it works a character at a time.

`os.path.dirname(path)`

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function `split()`.

`os.path.exists(path)`

Return True if *path* refers to an existing path. Returns False for broken symbolic links. On some platforms, this function may return False if permission is not granted to execute `os.stat()` on the requested file, even if the *path* physically exists.

`os.path.lexists(path)`

Return True if *path* refers to an existing path. Returns True for broken symbolic links. Equivalent to `exists()` on platforms lacking `os.lstat()`.

New in version 2.4.

`os.path.expanduser(path)`

On Unix and Windows, return the argument with an initial component of ~ or ~user replaced by that user's home directory.

On Unix, an initial ~ is replaced by the environment variable HOME if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module `pwd`. An initial ~user is looked up directly in the password directory.

On Windows, HOME and USERPROFILE will be used if set, otherwise a combination of HOMEPATH and HOMEDRIVE will be used. An initial ~user is handled by stripping the last directory component from the created user path derived above.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

`os.path.expandvars(path)`

Return the argument with environment variables expanded. Substrings of the form \$name or \${name} are replaced by the value of environment variable *name*. Malformed variable names and references to non-existing variables are left unchanged.

On Windows, %name% expansions are supported in addition to \$name and \${name}.

`os.path.getatime(path)`

Return the time of last access of *path*. The return value is a number giving the number of seconds since the epoch (see the `time` module). Raise `os.error` if the file does not exist or is inaccessible.

New in version 1.5.2.

Changed in version 2.3: If `os.stat_float_times()` returns True, the result is a floating point number.

`os.path.getmtime(path)`

Return the time of last modification of *path*. The return value is a number giving the number of seconds since the epoch (see the `time` module). Raise `os.error` if the file does not exist or is inaccessible.

New in version 1.5.2.

Changed in version 2.3: If `os.stat_float_times()` returns True, the result is a floating point number.

`os.path.getctime(path)`

Return the system's ctime which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the `time` module). Raise `os.error` if the file does not exist or is inaccessible.

New in version 2.3.

`os.path.getsize(path)`

Return the size, in bytes, of *path*. Raise `os.error` if the file does not exist or is inaccessible.

New in version 1.5.2.

`os.path.isabs(path)`

Return `True` if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with a (back)slash after chopping off a potential drive letter.

`os.path.isfile(path)`

Return `True` if *path* is an existing regular file. This follows symbolic links, so both `islink()` and `isfile()` can be true for the same path.

`os.path.isdir(path)`

Return `True` if *path* is an existing directory. This follows symbolic links, so both `islink()` and `isdir()` can be true for the same path.

`os.path.islink(path)`

Return `True` if *path* refers to a directory entry that is a symbolic link. Always `False` if symbolic links are not supported by the Python runtime.

`os.path.ismount(path)`

Return `True` if pathname *path* is a *mount point*: a point in a file system where a different file system has been mounted. The function checks whether *path*'s parent, `path/..`, is on a different device than *path*, or whether `path/..` and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants.

`os.path.join(path, *paths)`

Join one or more path components intelligently. The return value is the concatenation of *path* and any members of **paths* with exactly one directory separator (`os.sep`) following each non-empty part except the last, meaning that the result will only end in a separator if the last part is empty. If a component is an absolute path, all previous components are thrown away and joining continues from the absolute path component.

On Windows, the drive letter is not reset when an absolute path component (e.g., `r'foo'`) is encountered. If a component contains a drive letter, all previous components are thrown away and the drive letter is reset. Note that since there is a current directory for each drive, `os.path.join("c:", "foo")` represents a path relative to the current directory on drive C: (`c:foo`), not `c:\foo`.

`os.path.normcase(path)`

Normalize the case of a pathname. On Unix and Mac OS X, this returns the path unchanged; on case-insensitive filesystems, it converts the path to lowercase. On Windows, it also converts forward slashes to backward slashes.

`os.path.normpath(path)`

Normalize a pathname by collapsing redundant separators and up-level references so that `A//B`, `A/B/`, `A/./B` and `A/foo/./B` all become `A/B`. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use `normcase()`.

`os.path.realpath(path)`

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system).

New in version 2.2.

`os.path.relpath(path[, start])`

Return a relative filepath to *path* either from the current directory or from an optional *start* directory. This is a path computation: the filesystem is not accessed to confirm the existence or nature of *path* or *start*.

start defaults to `os.curdir`.

Availability: Windows, Unix.

New in version 2.6.

`os.path.samefile(path1, path2)`

Return True if both pathname arguments refer to the same file or directory (as indicated by device number and i-node number). Raise an exception if an `os.stat()` call on either pathname fails.

Availability: Unix.

`os.path.sameopenfile(fp1, fp2)`

Return True if the file descriptors `fp1` and `fp2` refer to the same file.

Availability: Unix.

`os.path.samestat(stat1, stat2)`

Return True if the stat tuples `stat1` and `stat2` refer to the same file. These structures may have been returned by `os.fstat()`, `os.lstat()`, or `os.stat()`. This function implements the underlying comparison used by `samefile()` and `sameopenfile()`.

Availability: Unix.

`os.path.split(path)`

Split the pathname `path` into a pair, (`head`, `tail`) where `tail` is the last pathname component and `head` is everything leading up to that. The `tail` part will never contain a slash; if `path` ends in a slash, `tail` will be empty. If there is no slash in `path`, `head` will be empty. If `path` is empty, both `head` and `tail` are empty. Trailing slashes are stripped from `head` unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as `path` (but the strings may differ). Also see the functions `dirname()` and `basename()`.

`os.path.splitdrive(path)`

Split the pathname `path` into a pair (`drive`, `tail`) where `drive` is either a drive specification or the empty string. On systems which do not use drive specifications, `drive` will always be the empty string. In all cases, `drive + tail` will be the same as `path`.

New in version 1.3.

`os.path.splitext(path)`

Split the pathname `path` into a pair (`root`, `ext`) such that `root + ext == path`, and `ext` is empty or begins with a period and contains at most one period. Leading periods on the basename are ignored; `splitext('.cshrc')` returns `('cshrc', '')`.

Changed in version 2.6: Earlier versions could produce an empty root when the only period was the first character.

`os.path.splitunc(path)`

Split the pathname `path` into a pair (`unc`, `rest`) so that `unc` is the UNC mount point (such as `r'\\host\mount'`), if present, and `rest` the rest of the path (such as `r'\path\file.ext'`). For paths containing drive letters, `unc` will always be the empty string.

Availability: Windows.

`os.path.walk(path, visit, arg)`

Calls the function `visit` with arguments (`arg`, `dirname`, `names`) for each directory in the directory tree rooted at `path` (including `path` itself, if it is a directory). The argument `dirname` specifies the visited directory, the argument `names` lists the files in the directory (gotten from `os.listdir(dirname)`). The `visit` function may modify `names` to influence the set of directories visited below `dirname`, e.g. to avoid visiting certain parts of the tree. (The object referred to by `names` must be modified in place, using `del` or slice assignment.)

Note: Symbolic links to directories are not treated as subdirectories, and that `walk()` therefore will not visit them. To visit linked directories you must identify them with `os.path.islink(file)` and `os.path.isdir(file)`, and invoke `walk()` as necessary.

Note: This function is deprecated and has been removed in Python 3 in favor of `os.walk()`.

`os.path.supports_unicode_filenames`

True if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

New in version 2.3.

10.2 fileinput — Iterate over lines from multiple input streams

Source code: [Lib/fileinput.py](#)

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see `open()`.

The typical use is:

```
import fileinput
for line in fileinput.input():
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is `'-'`, it is also replaced by `sys.stdin`. To specify an alternative list of filenames, pass it as the first argument to `input()`. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the `mode` parameter in the call to `input()` or `FileInput()`. If an I/O error occurs during opening or reading a file, `IOError` is raised.

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the `openhook` parameter to `fileinput.input()` or `FileInput()`. The hook must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. Two useful hooks are already provided by this module.

The following function is the primary interface of this module:

`fileinput.input([files[, inplace[, backup[, bufsize[, mode[, openhook]]]])`

Create an instance of the `FileInput` class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the `FileInput` class.

Changed in version 2.5: Added the `mode` and `openhook` parameters.

Changed in version 2.7.12: The `bufsize` parameter is no longer used.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

`fileinput.filename()`

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.fileeno()`

Return the integer “file descriptor” for the current file. When no file is opened (before the first line and between files), returns `-1`.

New in version 2.5.

`fileinput.lineno()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

`fileinput.filelineno()`

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.isfirstline()`

Returns true if the line just read is the first line of its file, otherwise returns false.

`fileinput.isstdin()`

Returns true if the last line was read from `sys.stdin`, otherwise returns false.

`fileinput.nextfile()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

`fileinput.close()`

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

class `fileinput.FileInput` (`[files[, inplace[, backup[, bufsize[, mode[, openhook]]]]]`)

Class `FileInput` is the implementation; its methods `filename()`, `fileeno()`, `lineno()`, `filelineno()`, `isfirstline()`, `isstdin()`, `nextfile()` and `close()` correspond to the functions of the same name in the module. In addition it has a `readline()` method which returns the next input line, and a `__getitem__()` method which implements the sequence behavior. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With `mode` you can specify which file mode will be passed to `open()`. It must be one of `'r'`, `'rU'`, `'U'` and `'rb'`.

The `openhook`, when given, must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. You cannot use `inplace` and `openhook` together.

Changed in version 2.5: Added the `mode` and `openhook` parameters.

Changed in version 2.7.12: The `bufsize` parameter is no longer used.

Optional in-place filtering: if the keyword argument `inplace=1` is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the `backup` parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

Note: The current implementation does not work for MS-DOS 8+3 filesystems.

The two following opening hooks are provided by this module:

`fileinput.hook_compressed(filename, mode)`

Transparently opens files compressed with `gzip` and `bzip2` (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed)`

New in version 2.5.

`fileinput.hook_encoded(encoding)`

Returns a hook which opens each file with `io.open()`, using the given `encoding` to read the file.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("iso-8859-1"))`

Note: With this hook, `FileInput` might return Unicode strings depending on the specified `encoding`.

New in version 2.5.

10.3 stat — Interpreting `stat()` results

Source code: [Lib/stat.py](#)

The `stat` module defines constants and functions for interpreting the results of `os.stat()`, `os.fstat()` and `os.lstat()` (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

The `stat` module defines the following functions to test for specific file types:

`stat.S_ISDIR(mode)`

Return non-zero if the mode is from a directory.

`stat.S_ISCHR(mode)`

Return non-zero if the mode is from a character special device file.

`stat.S_ISBLK(mode)`

Return non-zero if the mode is from a block special device file.

`stat.S_ISREG(mode)`

Return non-zero if the mode is from a regular file.

`stat.S_ISFIFO(mode)`

Return non-zero if the mode is from a FIFO (named pipe).

`stat.S_ISLNK(mode)`

Return non-zero if the mode is from a symbolic link.

`stat.S_ISSOCK(mode)`

Return non-zero if the mode is from a socket.

Two additional functions are defined for more general manipulation of the file's mode:

`stat.S_IMODE(mode)`

Return the portion of the file's mode that can be set by `os.chmod()`—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

`stat.S_IFMT(mode)`

Return the portion of the file's mode that describes the file type (used by the `S_IS*`() functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by `os.path`, like the tests for block and character devices.

Example:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
    calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.stat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print 'Skipping %s' % pathname

def visitfile(file):
    print 'visiting', file

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`

 Inode protection mode.

`stat.ST_INO`

 Inode number.

`stat.ST_DEV`

 Device inode resides on.

`stat.ST_NLINK`

 Number of links to the inode.

`stat.ST_UID`

 User id of the owner.

`stat.ST_GID`

 Group id of the owner.

`stat.ST_SIZE`

 Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`

 Time of last access.

`stat.ST_MTIME`

Time of last modification.

`stat.ST_CTIME`

The “ctime” as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of “file size” changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the “size” is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags:

`stat.S_IFSOCK`

Socket.

`stat.S_IFLNK`

Symbolic link.

`stat.S_IFREG`

Regular file.

`stat.S_IFBLK`

Block device.

`stat.S_IFDIR`

Directory.

`stat.S_IFCHR`

Character device.

`stat.S_IFIFO`

FIFO.

The following flags can also be used in the *mode* argument of `os.chmod()`:

`stat.S_ISUID`

Set UID bit.

`stat.S_ISGID`

Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the `S_ISGID` bit set. For a file that does not have the group execution bit (`S_IXGRP`) set, the set-group-ID bit indicates mandatory file/record locking (see also `S_ENFMT`).

`stat.S_ISVTX`

Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

`stat.S_IRWXU`

Mask for file owner permissions.

`stat.S_IRUSR`

Owner has read permission.

`stat.S_IWUSR`

Owner has write permission.

`stat.S_IXUSR`
Owner has execute permission.

`stat.S_IRWXG`
Mask for group permissions.

`stat.S_IRGRP`
Group has read permission.

`stat.S_IWGRP`
Group has write permission.

`stat.S_IXGRP`
Group has execute permission.

`stat.S_IRWXO`
Mask for permissions for others (not in group).

`stat.S_IROTH`
Others have read permission.

`stat.S_IWOTH`
Others have write permission.

`stat.S_IXOTH`
Others have execute permission.

`stat.S_ENFMT`
System V file locking enforcement. This flag is shared with `S_ISGID`: file/record locking is enforced on files that do not have the group execution bit (`S_IXGRP`) set.

`stat.S_IREAD`
Unix V7 synonym for `S_IRUSR`.

`stat.S_IWRITE`
Unix V7 synonym for `S_IWUSR`.

`stat.S_IXEXEC`
Unix V7 synonym for `S_IXUSR`.

The following flags can be used in the *flags* argument of `os.chflags()`:

`stat.UF_NODUMP`
Do not dump the file.

`stat.UF_IMMUTABLE`
The file may not be changed.

`stat.UF_APPEND`
The file may only be appended to.

`stat.UF_OPAQUE`
The directory is opaque when viewed through a union stack.

`stat.UF_NOUNLINK`
The file may not be renamed or deleted.

`stat.UF_COMPRESSED`
The file is stored compressed (Mac OS X 10.6+).

`stat.UF_HIDDEN`
The file should not be displayed in a GUI (Mac OS X 10.5+).

`stat.SF_ARCHIVED`

The file may be archived.

`stat.SF_IMMUTABLE`

The file may not be changed.

`stat.SF_APPEND`

The file may only be appended to.

`stat.SF_NOUNLINK`

The file may not be renamed or deleted.

`stat.SF_SNAPSHOT`

The file is a snapshot file.

See the *BSD or Mac OS systems man page *chflags(2)* for more information.

10.4 `statvfs` — Constants used with `os.statvfs()`

Deprecated since version 2.6: The `statvfs` module has been removed in Python 3.

The `statvfs` module defines constants so interpreting the result if `os.statvfs()`, which returns a tuple, can be made without remembering “magic numbers.” Each of the constants defined in this module is the *index* of the entry in the tuple returned by `os.statvfs()` that contains the specified information.

`statvfs.F_BSIZE`

Preferred file system block size.

`statvfs.F_FRSIZE`

Fundamental file system block size.

`statvfs.F_BLOCKS`

Total number of blocks in the filesystem.

`statvfs.F_BFREE`

Total number of free blocks.

`statvfs.F_BAVAIL`

Free blocks available to non-super user.

`statvfs.F_FILES`

Total number of file nodes.

`statvfs.F_FFREE`

Total number of free file nodes.

`statvfs.F_FAVAIL`

Free nodes available to non-super user.

`statvfs.F_FLAG`

Flags. System dependent: see `statvfs()` man page.

`statvfs.F_NAMEMAX`

Maximum file name length.

10.5 `filecmp` — File and Directory Comparisons

Source code: [Lib/filecmp.py](#)

The `filecmp` module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the `difflib` module.

The `filecmp` module defines the following functions:

`filecmp.cmp(f1, f2[, shallow])`

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

Unless *shallow* is given and is false, files with identical `os.stat()` signatures are taken to be equal.

Files that were compared using this function will not be compared again unless their `os.stat()` signature changes.

Note that no external programs are called from this function, giving it portability and efficiency.

`filecmp.cmpfiles(dir1, dir2, common[, shallow])`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for `filecmp.cmp()`.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare *a/c* with *b/c* and *a/d/e* with *b/d/e*. *'c'* and *'d/e'* will each be in one of the three returned lists.

Example:

```
>>> import filecmp
>>> filecmp.cmp('undoc.rst', 'undoc.rst')
True
>>> filecmp.cmp('undoc.rst', 'index.rst')
False
```

10.5.1 The `dircmp` class

`dircmp` instances are built using this constructor:

class `filecmp.dircmp(a, b[, ignore[, hide]])`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to `['RCS', 'CVS', 'tags']`. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The `dircmp` class compares files by doing *shallow* comparisons as described for `filecmp.cmp()`.

The `dircmp` class provides the following methods:

report()

Print (to `sys.stdout`) a comparison between *a* and *b*.

report_partial_closure()

Print a comparison between *a* and *b* and common immediate subdirectories.

report_full_closure()

Print a comparison between *a* and *b* and common subdirectories (recursively).

The `dircmp` class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

left

The directory *a*.

right

The directory *b*.

left_list

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

right_list

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

common

Files and subdirectories in both *a* and *b*.

left_only

Files and subdirectories only in *a*.

right_only

Files and subdirectories only in *b*.

common_dirs

Subdirectories in both *a* and *b*.

common_files

Files in both *a* and *b*

common_funny

Names in both *a* and *b*, such that the type differs between the directories, or names for which `os.stat()` reports an error.

same_files

Files which are identical in both *a* and *b*, using the class's file comparison operator.

diff_files

Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

funny_files

Files which are in both *a* and *b*, but could not be compared.

subdirs

A dictionary mapping names in `common_dirs` to `dircmp` objects.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print "diff_file %s found in %s and %s" % (name, dcmp.left,
...             dcmp.right)
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

10.6 `tempfile` — Generate temporary files and directories

Source code: [Lib/tempfile.py](#)

This module generates temporary files and directories. It works on all supported platforms.

In version 2.3 of Python, this module was overhauled for enhanced security. It now provides three new functions, `NamedTemporaryFile()`, `mkstemp()`, and `mkdtemp()`, which should eliminate all remaining need to use the insecure `mktemp()` function. Temporary file names created by this module no longer contain the process ID; instead a string of six random characters is used.

Also, all the user-callable functions now take additional arguments which allow direct control over the location and name of temporary files. It is no longer necessary to use the global `tempdir` and `template` variables. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable functions:

```
tempfile.TemporaryFile([mode='w+b', bufsize=-1, suffix='', prefix='tmp', dir=None])
```

Return a file-like object that can be used as a temporary storage area. The file is created using `mkstemp()`. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function having or not having a visible name in the file system.

The `mode` parameter defaults to `'w+b'` so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. `bufsize` defaults to `-1`, meaning that the operating system default is used.

The `dir`, `prefix` and `suffix` parameters are passed to `mkstemp()`.

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose `file` attribute is the underlying true file object. This file-like object can be used in a `with` statement, just like a normal file.

```
tempfile.NamedTemporaryFile([mode='w+b', bufsize=-1, suffix='', prefix='tmp', dir=None,
                             delete=True])
```

This function operates exactly as `TemporaryFile()` does, except that the file is guaranteed to have a visible name in the file system (on Unix, the directory entry is not unlinked). That name can be retrieved from the `name` attribute of the returned file-like object. Whether the name can be used to open the file a second time, while the named temporary file is still open, varies across platforms (it can be so used on Unix; it cannot on Windows NT or later). If `delete` is true (the default), the file is deleted as soon as it is closed.

The returned object is always a file-like object whose `file` attribute is the underlying true file object. This file-like object can be used in a `with` statement, just like a normal file.

New in version 2.3.

New in version 2.6: The `delete` parameter.

```
tempfile.SpooledTemporaryFile([max_size=0, mode='w+b', bufsize=-1, suffix='', pre-
                               fix='tmp', dir=None])
```

This function operates exactly as `TemporaryFile()` does, except that data is spooled in memory until the file size exceeds `max_size`, or until the file's `fileno()` method is called, at which point the contents are written to disk and operation proceeds as with `TemporaryFile()`. Also, its `truncate` method does not accept a `size` argument.

The resulting file has one additional method, `rollover()`, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose `_file` attribute is either a `StringIO` object or a true file object, depending on whether `rollover()` has been called. This file-like object can be used in a `with` statement, just like a normal file.

New in version 2.6.

```
tempfile.mkstemp([suffix="", prefix='tmp', dir=None, text=False])
```

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the `os.O_EXCL` flag for `os.open()`. The file is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If `suffix` is specified, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of `suffix`.

If `prefix` is specified, the file name will begin with that prefix; otherwise, a default prefix is used.

If `dir` is specified, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the `TMPDIR`, `TEMP` or `TMP` environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via `os.popen()`.

If `text` is specified, it indicates whether to open the file in binary mode (the default) or text mode. On some platforms, this makes no difference.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the absolute pathname of that file, in that order.

New in version 2.3.

```
tempfile.mkdtemp([suffix="", prefix='tmp', dir=None])
```

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The `prefix`, `suffix`, and `dir` arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory.

New in version 2.3.

```
tempfile.mktemp([suffix="", prefix='tmp', dir=None])
```

Deprecated since version 2.3: Use `mkstemp()` instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The `prefix`, `suffix`, and `dir` arguments are the same as for `mkstemp()`.

Warning: Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. `mktemp()` usage can be replaced easily with `NamedTemporaryFile()`, passing it the `delete=False` parameter:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f
<open file '<fdopen>', mode 'w+b' at 0x384698>
>>> f.name
'/var/folders/5q/5qTPn6xq2RaWqk+1Ytw3-U+++TI/-Tmp-/tmpG7V1Y0'
>>> f.write("Hello World!\n")
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
```

False

The module uses a global variable that tell it how to construct a temporary name. They are initialized at the first call to any of the functions above. The caller may change them, but this is discouraged; use the appropriate function arguments, instead.

`tempfile.tempdir`

When set to a value other than `None`, this variable defines the default value for the *dir* argument to all the functions defined in this module.

If `tempdir` is unset or `None` at any call to any of the above functions, Python searches a standard list of directories and sets *tempdir* to the first one which the calling user can create files in. The list is:

1. The directory named by the `TMPDIR` environment variable.
2. The directory named by the `TEMP` environment variable.
3. The directory named by the `TMP` environment variable.
4. A platform-specific location:
 - On RISCOS, the directory named by the `Wimp$ScrapDir` environment variable.
 - On Windows, the directories `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`, in that order.
 - On all other platforms, the directories `/tmp`, `/var/tmp`, and `/usr/tmp`, in that order.
5. As a last resort, the current working directory.

`tempfile.gettempdir()`

Return the directory currently selected to create temporary files in. If *tempdir* is not `None`, this simply returns its contents; otherwise, the search described above is performed, and the result returned.

New in version 2.3.

`tempfile.template`

Deprecated since version 2.0: Use `gettempprefix()` instead.

When set to a value other than `None`, this variable defines the prefix of the final component of the filenames returned by `mktemp()`. A string of six random letters and digits is appended to the prefix to make the filename unique. The default prefix is `tmp`.

Older versions of this module used to require that `template` be set to `None` after a call to `os.fork()`; this has not been necessary since version 1.5.2.

`tempfile.gettempprefix()`

Return the filename prefix used to create temporary files. This does not contain the directory component. Using this function is preferred over reading the *template* variable directly.

New in version 1.5.2.

10.7 glob — Unix style pathname pattern expansion

Source code: [Lib/glob.py](#)

The *glob* module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the `os.listdir()` and `fnmatch.fnmatch()` functions in concert, and not by actually invoking a subshell. Note that unlike `fnmatch.fnmatch()`, *glob* treats filenames

beginning with a dot (.) as special cases. (For tilde and shell variable expansion, use `os.path.expanduser()` and `os.path.expandvars()`.)

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

`glob.glob(pathname)`

Return a possibly-empty list of path names that match *pathname*, which must be a string containing a path specification. *pathname* can be either absolute (like `/usr/src/Python-1.5/Makefile`) or relative (like `.././Tools/*/*.gif`), and can contain shell-style wildcards. Broken symlinks are included in the results (as in the shell).

`glob.iglob(pathname)`

Return an *iterator* which yields the same values as `glob()` without actually storing them all simultaneously.

New in version 2.5.

For example, consider a directory containing only the following files: `1.gif`, `2.txt`, and `card.gif`. `glob()` will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
```

If the directory contains files starting with `.` they won't be matched by default. For example, consider a directory containing `card.gif` and `.card.gif`:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.c*')
['.card.gif']
```

Module `fnmatch` Shell-style filename (not path) expansion

10.8 fnmatch — Unix filename pattern matching

Source code: `Lib/fnmatch.py`

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the `re` module). The special characters used in shell-style wildcards are:

| Pattern | Meaning |
|---------------------|---|
| <code>*</code> | matches everything |
| <code>?</code> | matches any single character |
| <code>[seq]</code> | matches any character in <i>seq</i> |
| <code>[!seq]</code> | matches any character not in <i>seq</i> |

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module [glob](#) for pathname expansion ([glob](#) uses [filter\(\)](#) to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

`fnmatch.fnmatch(filename, pattern)`

Test whether the *filename* string matches the *pattern* string, returning *True* or *False*. Both parameters are case-normalized using `os.path.normcase()`. [fnmatchcase\(\)](#) can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print file
```

`fnmatch.fnmatchcase(filename, pattern)`

Test whether *filename* matches *pattern*, returning *True* or *False*; the comparison is case-sensitive and does not apply `os.path.normcase()`.

`fnmatch.filter(names, pattern)`

Return the subset of the list of *names* that match *pattern*. It is the same as `[n for n in names if fnmatch(n, pattern)]`, but implemented more efficiently.

New in version 2.2.

`fnmatch.translate(pattern)`

Return the shell-style *pattern* converted to a regular expression for using with [re.match\(\)](#).

Example:

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'.*\\.txt\\Z(?ms)'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<_sre.SRE_Match object at 0x...>
```

See also:

Module [glob](#) Unix shell-style path expansion.

10.9 linecache — Random access to text lines

Source code: [Lib/linecache.py](#)

The [linecache](#) module allows one to get any line from any file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the [traceback](#) module to retrieve source lines for inclusion in the formatted traceback.

The [linecache](#) module defines the following functions:

`linecache.getline(filename, lineno[, module_globals])`

Get line *lineno* from file named *filename*. This function will never raise an exception — it will return `' '` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function will look for it in the module search path, `sys.path`, after first checking for a [PEP 302](#) `__loader__` in *module_globals*, in case the module was imported from a zipfile or other non-filesystem import source.

New in version 2.5: The *module_globals* parameter was added.

`linecache.clearcache()`

Clear the cache. Use this function if you no longer need lines from files previously read using `getline()`.

`linecache.checkcache([filename])`

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

Example:

```
>>> import linecache
>>> linecache.getline('/etc/passwd', 4)
'sys:x:3:3:sys:/dev:/bin/sh\n'
```

10.10 shutil — High-level file operations

Source code: [Lib/shutil.py](#)

The *shutil* module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the *os* module.

Warning: Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) can't copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

10.10.1 Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the file-like object *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst)`

Copy the contents (no metadata) of the file named *src* to a file named *dst*. *dst* must be the complete target file name; look at `shutil.copy()` for a copy that accepts a target directory path. If *src* and *dst* are the same files, *Error* is raised. The destination location must be writable; otherwise, an *IOError* exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function. *src* and *dst* are path names given as strings.

`shutil.copymode(src, dst)`

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path names given as strings.

`shutil.copystat(src, dst)`

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path names given as strings.

`shutil.copy(src, dst)`

Copy the file *src* to the file or directory *dst*. If *dst* is a directory, a file with the same basename as *src* is created (or overwritten) in the directory specified. Permission bits are copied. *src* and *dst* are path names given as strings.

`shutil.copy2(src, dst)`

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

New in version 2.6.

`shutil.copytree(src, dst, symlinks=False, ignore=None)`

Recursively copy an entire directory tree rooted at *src*. The destination directory, named by *dst*, must not already exist; it will be created as well as missing parent directories. Permissions and times of directories are copied with `copystat()`, individual files are copied using `shutil.copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree, but the metadata of the original links is NOT copied; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

The source code for this should be considered an example rather than the ultimate tool.

Changed in version 2.3: `Error` is raised if any exceptions occur during copying, rather than printing a message.

Changed in version 2.5: Create intermediate directories needed to create *dst*, rather than raising an error. Copy permissions and times of directories using `copystat()`.

Changed in version 2.6: Added the *ignore* argument to be able to influence what is being copied.

`shutil.rmtree(path[, ignore_errors[, onerror]])`

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory). If *ignore_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onerror* or, if that is omitted, they raise an exception.

If *onerror* is provided, it must be a callable that accepts three parameters: *function*, *path*, and *excinfo*. The first parameter, *function*, is the function which raised the exception; it will be `os.path.islink()`, `os.listdir()`, `os.remove()` or `os.rmdir()`. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, will be the exception information return by `sys.exc_info()`. Exceptions raised by *onerror* will not be caught.

Changed in version 2.6: Explicitly check for *path* being a symbolic link and raise `OSError` in that case.

`shutil.move(src, dst)`

Recursively move a file or directory (*src*) to another location (*dst*).

If the destination is an existing directory, then *src* is moved inside that directory. If the destination already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied (using `shutil.copy2()`) to *dst* and then removed.

New in version 2.3.

exception `shutil.Error`

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

New in version 2.3.

copytree example

This example is the implementation of the `copytree()` function, described above, with the docstring omitted. It demonstrates many of the other functions provided by this module.

```
def copytree(src, dst, symlinks=False, ignore=None):
    names = os.listdir(src)
    if ignore is not None:
        ignored_names = ignore(src, names)
    else:
        ignored_names = set()

    os.makedirs(dst)
    errors = []
    for name in names:
        if name in ignored_names:
            continue
        srcname = os.path.join(src, name)
        dstname = os.path.join(dst, name)
        try:
            if symlinks and os.path.islink(srcname):
                linkto = os.readlink(srcname)
                os.symlink(linkto, dstname)
            elif os.path.isdir(srcname):
                copytree(srcname, dstname, symlinks, ignore)
            else:
                copy2(srcname, dstname)
            # XXX What about devices, sockets etc.?
        except (IOError, os.error) as why:
            errors.append((srcname, dstname, str(why)))
        # catch the Error from the recursive copytree so that we can
        # continue with other files
        except Error as err:
            errors.extend(err.args[0])
    try:
        copystat(src, dst)
    except WindowsError:
        # can't copy file access times on Windows
        pass
    except OSError as why:
        errors.extend((src, dst, str(why)))
```

(continues on next page)

(continued from previous page)

```
if errors:
    raise Error(errors)
```

Another example that uses the `ignore_patterns()` helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s' % path)
    return [] # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

10.10.2 Archiving operations

High-level utilities to create and read compressed and archived files are also provided. They rely on the `zipfile` and `tarfile` modules.

`shutil.make_archive(base_name, format[, root_dir[, base_dir[, verbose[, dry_run[, owner[, group[, logger]]]]]])`

Create an archive file (eg. zip or tar) and returns its name.

base_name is the name of the file to create, including the path, minus any format-specific extension. *format* is the archive format: one of “zip” (if the `zlib` module or external zip executable is available), “tar”, “gztar” (if the `zlib` module is available), or “bztar” (if the `bz2` module is available).

root_dir is a directory that will be the root directory of the archive; ie. we typically `chdir` into *root_dir* before creating the archive.

base_dir is the directory where we start archiving from; ie. *base_dir* will be the common prefix of all files and directories in the archive.

root_dir and *base_dir* both default to the current directory.

owner and *group* are used when creating a tar archive. By default, uses the current owner and group.

logger must be an object compatible with **PEP 282**, usually an instance of `logging.Logger`.

New in version 2.7.

`shutil.get_archive_formats()`

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple (name, description).

By default `shutil` provides these formats:

- *zip*: ZIP file (if the `zlib` module or external zip executable is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip’ed tar-file (if the `zlib` module is available).

- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

New in version 2.7.

`shutil.register_archive_format(name, function[, extra_args[, description]])`

Register an archiver for the format *name*. *function* is a callable that will be used to invoke the archiver.

If given, *extra_args* is a sequence of (name, value) that will be used as extra keywords arguments when the archiver callable is used.

description is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty list.

New in version 2.7.

`shutil.unregister_archive_format(name)`

Remove the archive format *name* from the list of supported formats.

New in version 2.7.

Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff    609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff     65 2008-06-09 13:26:54 ./config
-rwx----- tarek/staff    668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff    609 2008-06-09 13:26:54 ./id_dsa.pub
-rw----- tarek/staff   1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff    397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff  37192 2010-02-06 18:23:10 ./known_hosts
```

10.11 dircache — Cached directory listings

Deprecated since version 2.6: The *dircache* module has been removed in Python 3.

The *dircache* module defines a function for reading directory listing using a cache, and cache invalidation using the *mtime* of the directory. Additionally, it defines a function to annotate directories by appending a slash.

The *dircache* module defines the following functions:

`dircache.reset()`

Resets the directory cache.

`dircache.listdir(path)`

Return a directory listing of *path*, as gotten from `os.listdir()`. Note that unless *path* changes, further call to `listdir()` will not re-read the directory structure.

Note that the list returned should be regarded as read-only. (Perhaps a future version should change it to return a tuple?)

`dircache.opendir(path)`

Same as `listdir()`. Defined for backwards compatibility.

`dircache.annotate(head, list)`

Assume *list* is a list of paths relative to *head*, and append, in place, a '/' to each path which points to a directory.

```
>>> import dircache
>>> a = dircache.listdir('/')
>>> a = a[:] # Copy the return value so we can change 'a'
>>> a
['bin', 'boot', 'cdrom', 'dev', 'etc', 'floppy', 'home', 'initrd', 'lib', 'lost+
found', 'mnt', 'proc', 'root', 'sbin', 'tmp', 'usr', 'var', 'vmlinuz']
>>> dircache.annotate('/', a)
>>> a
['bin/', 'boot/', 'cdrom/', 'dev/', 'etc/', 'floppy/', 'home/', 'initrd/', 'lib/
', 'lost+found/', 'mnt/', 'proc/', 'root/', 'sbin/', 'tmp/', 'usr/', 'var/', 'vm
linuz']
```

10.12 macpath — Mac OS 9 path manipulation functions

This module is the Mac OS 9 (and earlier) implementation of the `os.path` module. It can be used to manipulate old-style Macintosh pathnames on Mac OS X (or any other platform).

The following functions are available in this module: `normcase()`, `normpath()`, `isabs()`, `join()`, `split()`, `isdir()`, `isfile()`, `walk()`, `exists()`. For other functions available in `os.path` dummy counterparts are available.

See also:

Section *File Objects* A description of Python's built-in file objects.

Module *os* Operating system interfaces, including functions to work with files at a lower level than the built-in file object.

DATA PERSISTENCE

The modules described in this chapter support storing Python data in a persistent form on disk. The `pickle` and `marshal` modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings. The `bsddb` module also provides such disk-based string-to-string mappings based on hashing, and also supports B-Tree and record-based formats.

The list of modules described in this chapter is:

11.1 `pickle` — Python object serialization

The `pickle` module implements a fundamental, but powerful algorithm for serializing and de-serializing a Python object structure. “Pickling” is the process whereby a Python object hierarchy is converted into a byte stream, and “unpickling” is the inverse operation, whereby a byte stream is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as “serialization”, “marshalling,”¹ or “flattening”, however, to avoid confusion, the terms used here are “pickling” and “unpickling”.

This documentation describes both the `pickle` module and the `cPickle` module.

Warning: The `pickle` module is not secure against erroneous or maliciously constructed data. Never unpickle data received from an untrusted or unauthenticated source.

11.1.1 Relationship to other Python modules

The `pickle` module has an optimized cousin called the `cPickle` module. As its name implies, `cPickle` is written in C, so it can be up to 1000 times faster than `pickle`. However it does not support subclassing of the `Pickler()` and `Unpickler()` classes, because in `cPickle` these are functions, not classes. Most applications have no need for this functionality, and can benefit from the improved performance of `cPickle`. Other than that, the interfaces of the two modules are nearly identical; the common interface is described in this manual and differences are pointed out where necessary. In the following discussions, we use the term “pickle” to collectively describe the `pickle` and `cPickle` modules.

The data streams the two modules produce are guaranteed to be interchangeable.

Python has a more primitive serialization module called `marshal`, but in general `pickle` should always be the preferred way to serialize Python objects. `marshal` exists primarily to support Python’s `.pyc` files.

The `pickle` module differs from `marshal` in several significant ways:

¹ Don’t confuse this with the `marshal` module

- The `pickle` module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. `marshal` doesn't do this.

This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by `marshal`, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the same object in different places in the object hierarchy being serialized. `pickle` stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.

- `marshal` cannot be used to serialize user-defined classes and their instances. `pickle` can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.
- The `marshal` serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The `pickle` serialization format is guaranteed to be backwards compatible across Python releases.

Note that serialization is a more primitive notion than persistence; although `pickle` reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The `pickle` module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The module `shelve` provides a simple interface to pickle and unpickle objects on DBM-style database files.

11.1.2 Data stream format

The data format used by `pickle` is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the `pickle` data format uses a printable ASCII representation. This is slightly more voluminous than a binary representation. The big advantage of using printable ASCII (and of some other characteristics of `pickle`'s representation) is that for debugging or recovery purposes it is possible for a human to read the pickled file with a standard text editor.

There are currently 3 different protocols which can be used for pickling.

- Protocol version 0 is the original ASCII protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is the old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*.

Refer to **PEP 307** for more information.

If a *protocol* is not specified, protocol 0 is used. If *protocol* is specified as a negative value or `HIGHEST_PROTOCOL`, the highest protocol version available will be used.

Changed in version 2.3: Introduced the *protocol* parameter.

A binary format, which is slightly more efficient, can be chosen by specifying a *protocol* version `>= 1`.

11.1.3 Usage

To serialize an object hierarchy, you first create a pickler, then you call the pickler's `dump()` method. To de-serialize a data stream, you first create an unpickler, then you call the unpickler's `load()` method. The `pickle` module provides the following constant:

`pickle.HIGHEST_PROTOCOL`

The highest protocol version available. This value can be passed as a *protocol* value.

New in version 2.3.

Note: Be sure to always open pickle files created with protocols ≥ 1 in binary mode. For the old ASCII-based pickle protocol 0 you can use either text mode or binary mode as long as you stay consistent.

A pickle file written with protocol 0 in binary mode will contain lone linefeeds as line terminators and therefore will look “funny” when viewed in Notepad or other editors which do not support this format.

The *pickle* module provides the following functions to make the pickling process more convenient:

`pickle.dump(obj, file[, protocol])`

Write a pickled representation of *obj* to the open file object *file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

If the *protocol* parameter is omitted, protocol 0 is used. If *protocol* is specified as a negative value or *HIGHEST_PROTOCOL*, the highest protocol version will be used.

Changed in version 2.3: Introduced the *protocol* parameter.

file must have a `write()` method that accepts a single string argument. It can thus be a file object opened for writing, a *StringIO* object, or any other custom object that meets this interface.

`pickle.load(file)`

Read a string from the open file object *file* and interpret it as a pickle data stream, reconstructing and returning the original object hierarchy. This is equivalent to `Unpickler(file).load()`.

file must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return a string. Thus *file* can be a file object opened for reading, a *StringIO* object, or any other custom object that meets this interface.

This function automatically determines whether the data stream was written in binary mode or not.

`pickle.dumps(obj[, protocol])`

Return the pickled representation of the object as a string, instead of writing it to a file.

If the *protocol* parameter is omitted, protocol 0 is used. If *protocol* is specified as a negative value or *HIGHEST_PROTOCOL*, the highest protocol version will be used.

Changed in version 2.3: The *protocol* parameter was added.

`pickle.loads(string)`

Read a pickled object hierarchy from a string. Characters in the string past the pickled object’s representation are ignored.

The *pickle* module also defines three exceptions:

exception `pickle.PickleError`

A common base class for the other exceptions defined below. This inherits from *Exception*.

exception `pickle.PicklingError`

This exception is raised when an unpicklable object is passed to the `dump()` method.

exception `pickle.UnpicklingError`

This exception is raised when there is a problem unpickling an object. Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) *AttributeError*, *EOFError*, *ImportError*, and *IndexError*.

The `pickle` module also exports two callables², `Pickler` and `Unpickler`:

class `pickle.Pickler` (*file* [, *protocol*])

This takes a file-like object to which it will write a pickle data stream.

If the *protocol* parameter is omitted, protocol 0 is used. If *protocol* is specified as a negative value or `HIGHEST_PROTOCOL`, the highest protocol version will be used.

Changed in version 2.3: Introduced the *protocol* parameter.

file must have a `write()` method that accepts a single string argument. It can thus be an open file object, a `StringIO` object, or any other custom object that meets this interface.

`Pickler` objects define one (or two) public methods:

dump (*obj*)

Write a pickled representation of *obj* to the open file object given in the constructor. Either the binary or ASCII format will be used, depending on the value of the *protocol* argument passed to the constructor.

clear_memo ()

Clears the pickler's "memo". The memo is the data structure that remembers which objects the pickler has already seen, so that shared or recursive objects pickled by reference and not by value. This method is useful when re-using picklers.

Note: Prior to Python 2.3, `clear_memo()` was only available on the picklers created by `cPickle`. In the `pickle` module, picklers have an instance variable called `memo` which is a Python dictionary. So to clear the memo for a `pickle` module pickler, you could do the following:

```
mypickler.memo.clear()
```

Code that does not need to support older versions of Python should simply use `clear_memo()`.

It is possible to make multiple calls to the `dump()` method of the same `Pickler` instance. These must then be matched to the same number of calls to the `load()` method of the corresponding `Unpickler` instance. If the same object is pickled by multiple `dump()` calls, the `load()` will all yield references to the same object.³

`Unpickler` objects are defined as:

class `pickle.Unpickler` (*file*)

This takes a file-like object from which it will read a pickle data stream. This class automatically determines whether the data stream was written in binary mode or not, so it does not need a flag as in the `Pickler` factory.

file must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return a string. Thus *file* can be a file object opened for reading, a `StringIO` object, or any other custom object that meets this interface.

`Unpickler` objects have one (or two) public methods:

load ()

Read a pickled object representation from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein.

This method automatically determines whether the data stream was written in binary mode or not.

² In the `pickle` module these callables are classes, which you could subclass to customize the behavior. However, in the `cPickle` module these callables are factory functions and so cannot be subclassed. One common reason to subclass is to control what objects can actually be unpickled. See section *Subclassing Unpicklers* for more details.

³ *Warning:* this is intended for pickling multiple objects without intervening modifications to the objects or their parts. If you modify an object and then pickle it again using the same `Pickler` instance, the object is not pickled again — a reference to it is pickled and the `Unpickler` will return the old value, not the modified one. There are two problems here: (1) detecting changes, and (2) marshalling a minimal set of changes. Garbage Collection may also become a problem here.

noload()

This is just like `load()` except that it doesn't actually create any objects. This is useful primarily for finding what's called "persistent ids" that may be referenced in a pickle data stream. See section [The pickle protocol](#) below for more details.

Note: the `noload()` method is currently only available on `Unpickler` objects created with the `cPickle` module. `pickle` module `Unpicklers` do not have the `noload()` method.

11.1.4 What can be pickled and unpickled?

The following types can be pickled:

- `None`, `True`, and `False`
- integers, long integers, floating point numbers, complex numbers
- normal and Unicode strings
- tuples, lists, sets, and dictionaries containing only picklable objects
- functions defined at the top level of a module
- built-in functions defined at the top level of a module
- classes that are defined at the top level of a module
- instances of such classes whose `__dict__` or the result of calling `__getstate__()` is picklable (see section [The pickle protocol](#) for details).

Attempts to pickle unpicklable objects will raise the `PicklingError` exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a `RuntimeError` will be raised in this case. You can carefully raise this limit with `sys.setrecursionlimit()`.

Note that functions (built-in and user-defined) are pickled by "fully qualified" name reference, not by value. This means that only the function name is pickled, along with the name of the module the function is defined in. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.⁴

Similarly, classes are pickled by named reference, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'a class attr'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined in the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class's `__setstate__()` method.

⁴ The exception raised will likely be an `ImportError` or an `AttributeError` but it could be something else.

11.1.5 The pickle protocol

This section describes the “pickling protocol” that defines the interface between the pickler/unpickler and the objects that are being serialized. This protocol provides a standard way for you to define, customize, and control how your objects are serialized and de-serialized. The description in this section doesn’t cover specific customizations that you can employ to make the unpickling environment slightly safer from untrusted pickle data streams; see section *Subclassing Unpicklers* for more details.

Pickling and unpickling normal class instances

`object.__getinitargs__()`

When a pickled class instance is unpickled, its `__init__()` method is normally *not* invoked. If it is desirable that the `__init__()` method be called on unpickling, an old-style class can define a method `__getinitargs__()`, which should return a *tuple* of positional arguments to be passed to the class constructor (`__init__()` for example). Keyword arguments are not supported. The `__getinitargs__()` method is called at pickle time; the tuple it returns is incorporated in the pickle for the instance.

`object.__getnewargs__()`

New-style types can provide a `__getnewargs__()` method that is used for protocol 2. Implementing this method is needed if the type establishes some internal invariants when the instance is created, or if the memory allocation is affected by the values passed to the `__new__()` method for the type (as it is for tuples and strings). Instances of a *new-style class* `C` are created using

```
obj = C.__new__(C, *args)
```

where `args` is the result of calling `__getnewargs__()` on the original object; if there is no `__getnewargs__()`, an empty tuple is assumed.

`object.__getstate__()`

Classes can further influence how their instances are pickled; if the class defines the method `__getstate__()`, it is called and the return state is pickled as the contents for the instance, instead of the contents of the instance’s dictionary. If there is no `__getstate__()` method, the instance’s `__dict__` is pickled.

`object.__setstate__(state)`

Upon unpickling, if the class also defines the method `__setstate__()`, it is called with the unpickled state.⁵ If there is no `__setstate__()` method, the pickled state must be a dictionary and its items are assigned to the new instance’s dictionary. If a class defines both `__getstate__()` and `__setstate__()`, the state object needn’t be a dictionary and these methods can do what they want.⁶

Note: For *new-style classes*, if `__getstate__()` returns a false value, the `__setstate__()` method will not be called.

Note: At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement either `__getinitargs__()` or `__getnewargs__()` to establish such an invariant; otherwise, neither `__new__()` nor `__init__()` will be called.

⁵ These methods can also be used to implement copying class instances.

⁶ This protocol is also used by the shallow and deep copying operations defined in the `copy` module.

Pickling and unpickling extension types

`object.__reduce__()`

When the `Pickler` encounters an object of a type it knows nothing about — such as an extension type — it looks in two places for a hint of how to pickle it. One alternative is for the object to implement a `__reduce__()` method. If provided, at pickling time `__reduce__()` will be called with no arguments, and it must return either a string or a tuple.

If a string is returned, it names a global variable whose contents are pickled as normal. The string returned by `__reduce__()` should be the object’s local name relative to its module; the pickle module searches the module namespace to determine the object’s module.

When a tuple is returned, it must be between two and five elements long. Optional elements can either be omitted, or `None` can be provided as their value. The contents of this tuple are pickled as normal and used to reconstruct the object at unpickling time. The semantics of each element are:

- A callable object that will be called to create the initial version of the object. The next element of the tuple will provide arguments for this callable, and later elements provide additional state information that will subsequently be used to fully reconstruct the pickled data.

In the unpickling environment this object must be either a class, a callable registered as a “safe constructor” (see below), or it must have an attribute `__safe_for_unpickling__` with a true value. Otherwise, an `UnpicklingError` will be raised in the unpickling environment. Note that as usual, the callable itself is pickled by name.

- A tuple of arguments for the callable object.

Changed in version 2.5: Formerly, this argument could also be `None`.

- Optionally, the object’s state, which will be passed to the object’s `__setstate__()` method as described in section *Pickling and unpickling normal class instances*. If the object has no `__setstate__()` method, then, as above, the value must be a dictionary and it will be added to the object’s `__dict__`.
- Optionally, an iterator (and not a sequence) yielding successive list items. These list items will be pickled, and appended to the object using either `obj.append(item)` or `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive dictionary items, which should be tuples of the form `(key, value)`. These items will be pickled and stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.

`object.__reduce_ex__(protocol)`

It is sometimes useful to know the protocol version when implementing `__reduce__()`. This can be done by implementing a method named `__reduce_ex__()` instead of `__reduce__()`. `__reduce_ex__()`, when it exists, is called in preference over `__reduce__()` (you may still provide `__reduce__()` for backwards compatibility). The `__reduce_ex__()` method will be called with a single integer argument, the protocol version.

The `object` class implements both `__reduce__()` and `__reduce_ex__()`; however, if a subclass overrides `__reduce__()` but not `__reduce_ex__()`, the `__reduce_ex__()` implementation detects this and calls `__reduce__()`.

An alternative to implementing a `__reduce__()` method on the object to be pickled, is to register the callable with the `copy_reg` module. This module provides a way for programs to register “reduction functions” and constructors for user-defined types. Reduction functions have the same semantics and interface as the `__reduce__()` method described above, except that they are called with a single argument, the object to be pickled.

The registered constructor is deemed a “safe constructor” for purposes of unpickling as described above.

Pickling and unpickling external objects

For the benefit of object persistence, the `pickle` module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a “persistent id”, which is just an arbitrary string of printable ASCII characters. The resolution of such names is not defined by the `pickle` module; it will delegate this resolution to user defined functions on the pickler and unpickler.⁷

To define external persistent id resolution, you need to set the `persistent_id` attribute of the pickler object and the `persistent_load` attribute of the unpickler object.

To pickle objects that have an external persistent id, the pickler must have a custom `persistent_id()` method that takes an object as an argument and returns either `None` or the persistent id for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent id string is returned, the pickler will pickle that string, along with a marker so that the unpickler will recognize the string as a persistent id.

To unpickle external objects, the unpickler must have a custom `persistent_load()` function that takes a persistent id string and returns the referenced object.

Here’s a silly example that *might* shed more light:

```
import pickle
from cStringIO import StringIO

src = StringIO()
p = pickle.Pickler(src)

def persistent_id(obj):
    if hasattr(obj, 'x'):
        return 'the value %d' % obj.x
    else:
        return None

p.persistent_id = persistent_id

class Integer:
    def __init__(self, x):
        self.x = x
    def __str__(self):
        return 'My name is integer %d' % self.x

i = Integer(7)
print i
p.dump(i)

datastream = src.getvalue()
print repr(datastream)
dst = StringIO(datastream)

up = pickle.Unpickler(dst)

class FancyInteger(Integer):
    def __str__(self):
```

(continues on next page)

⁷ The actual mechanism for associating these user defined functions is slightly different for `pickle` and `cPickle`. The description given here works the same for both implementations. Users of the `pickle` module could also use subclassing to effect the same results, overriding the `persistent_id()` and `persistent_load()` methods in the derived classes.

(continued from previous page)

```

        return 'I am the integer %d' % self.x

def persistent_load(persid):
    if persid.startswith('the value '):
        value = int(persid.split()[2])
        return FancyInteger(value)
    else:
        raise pickle.UnpicklingError, 'Invalid persistent id'

up.persistent_load = persistent_load

j = up.load()
print j

```

In the `cPickle` module, the unpickler's `persistent_load` attribute can also be set to a Python list, in which case, when the unpickler reaches a persistent id, the persistent id string will simply be appended to this list. This functionality exists so that a pickle data stream can be “sniffed” for object references without actually instantiating all the objects in a pickle.⁸ Setting `persistent_load` to a list is usually used in conjunction with the `noload()` method on the Unpickler.

11.1.6 Subclassing Unpicklers

By default, unpickling will import any class that it finds in the pickle data. You can control exactly what gets unpickled and what gets called by customizing your unpickler. Unfortunately, exactly how you do this is different depending on whether you're using `pickle` or `cPickle`.⁹

In the `pickle` module, you need to derive a subclass from `Unpickler`, overriding the `load_global()` method. `load_global()` should read two lines from the pickle data stream where the first line will be the name of the module containing the class and the second line will be the name of the instance's class. It then looks up the class, possibly importing the module and digging out the attribute, then it appends what it finds to the unpickler's stack. Later on, this class will be assigned to the `__class__` attribute of an empty class, as a way of magically creating an instance without calling its class's `__init__()`. Your job (should you choose to accept it), would be to have `load_global()` push onto the unpickler's stack, a known safe version of any class you deem safe to unpickle. It is up to you to produce such a class. Or you could raise an error if you want to disallow all unpickling of instances. If this sounds like a hack, you're right. Refer to the source code to make this work.

Things are a little cleaner with `cPickle`, but not by much. To control what gets unpickled, you can set the unpickler's `find_global` attribute to a function or `None`. If it is `None` then any attempts to unpickle instances will raise an `UnpicklingError`. If it is a function, then it should accept a module name and a class name, and return the corresponding class object. It is responsible for looking up the class and performing any necessary imports, and it may raise an error to prevent instances of the class from being unpickled.

The moral of the story is that you should be really careful about the source of the strings your application unpickles.

11.1.7 Example

For the simplest code, use the `dump()` and `load()` functions. Note that a self-referencing list is pickled and restored correctly.

⁸ We'll leave you with the image of Guido and Jim sitting around sniffing pickles in their living rooms.

⁹ A word of caution: the mechanisms described here use internal attributes and methods, which are subject to change in future versions of Python. We intend to someday provide a common interface for controlling this behavior, which will work in either `pickle` or `cPickle`.

```
import pickle

data1 = {'a': [1, 2.0, 3, 4+6j],
        'b': ('string', u'Unicode string'),
        'c': None}

selfref_list = [1, 2, 3]
selfref_list.append(selfref_list)

output = open('data.pkl', 'wb')

# Pickle dictionary using protocol 0.
pickle.dump(data1, output)

# Pickle the list using the highest protocol available.
pickle.dump(selfref_list, output, -1)

output.close()
```

The following example reads the resulting pickled data. When reading a pickle-containing file, you should open the file in binary mode because you can't be sure if the ASCII or binary format was used.

```
import pprint, pickle

pkl_file = open('data.pkl', 'rb')

data1 = pickle.load(pkl_file)
pprint.pprint(data1)

data2 = pickle.load(pkl_file)
pprint.pprint(data2)

pkl_file.close()
```

Here's a larger example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
#!/usr/local/bin/python

class TextReader:
    """Print and number lines in a text file."""
    def __init__(self, file):
        self.file = file
        self.fh = open(file)
        self.lineno = 0

    def readline(self):
        self.lineno = self.lineno + 1
        line = self.fh.readline()
        if not line:
            return None
        if line.endswith("\n"):
            line = line[:-1]
        return "%d: %s" % (self.lineno, line)
```

(continues on next page)

(continued from previous page)

```

def __getstate__(self):
    odict = self.__dict__.copy() # copy the dict since we change it
    del odict['fh']               # remove filehandle entry
    return odict

def __setstate__(self, dict):
    fh = open(dict['file'])       # reopen file
    count = dict['lineno']        # read from file...
    while count:                 # until line count is restored
        fh.readline()
        count = count - 1
    self.__dict__.update(dict)   # update attributes
    self.fh = fh                 # save the file object

```

A sample usage might be something like this:

```

>>> import TextReader
>>> obj = TextReader.TextReader("TextReader.py")
>>> obj.readline()
'1: #!/usr/local/bin/python'
>>> obj.readline()
'2: '
>>> obj.readline()
'3: class TextReader:'
>>> import pickle
>>> pickle.dump(obj, open('save.p', 'wb'))

```

If you want to see that *pickle* works across Python processes, start another Python session, before continuing. What follows can happen from either the same process or a new process.

```

>>> import pickle
>>> reader = pickle.load(open('save.p', 'rb'))
>>> reader.readline()
'4:     """Print and number lines in a text file."""'

```

Module *copy_reg* Pickle interface constructor registration for extension types.

Module *shelve* Indexed databases of objects; uses *pickle*.

Module *copy* Shallow and deep object copying.

Module *marshal* High-performance serialization of built-in types.

11.2 cPickle — A faster pickle

The *cPickle* module supports serialization and de-serialization of Python objects, providing an interface and functionality nearly identical to the *pickle* module. There are several differences, the most important being performance and subclassability.

First, *cPickle* can be up to 1000 times faster than *pickle* because the former is implemented in C. Second, in the *cPickle* module the callables *Pickler*() and *Unpickler*() are functions, not classes. This means that you cannot use them to derive custom pickling and unpickling subclasses. Most applications have no need for this functionality and should benefit from the greatly improved performance of the *cPickle* module.

The pickle data stream produced by `pickle` and `cPickle` are identical, so it is possible to use `pickle` and `cPickle` interchangeably with existing pickles.¹⁰

There are additional minor differences in API between `cPickle` and `pickle`, however for most applications, they are interchangeable. More documentation is provided in the `pickle` module documentation, which includes a list of the documented differences.

11.3 copy_reg — Register pickle support functions

Note: The `copy_reg` module has been renamed to `copyreg` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

The `copy_reg` module offers a way to define functions used while pickling specific objects. The `pickle`, `cPickle`, and `copy` modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

`copy_reg.constructor` (*object*)

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises `TypeError`.

`copy_reg.pickle` (*type*, *function* [, *constructor*])

Declares that *function* should be used as a “reduction” function for objects of type *type*; *type* must not be a “classic” class object. (Classic classes are handled differently; see the documentation for the `pickle` module for details.) *function* should return either a string or a tuple containing two or three elements.

The optional *constructor* parameter, if provided, is a callable object which can be used to reconstruct the object when called with the tuple of arguments returned by *function* at pickling time. `TypeError` will be raised if *object* is a class or *constructor* is not callable.

See the `pickle` module for more details on the interface expected of *function* and *constructor*.

11.3.1 Example

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copy_reg, copy, pickle
>>> class C(object):
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copy_reg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
```

(continues on next page)

¹⁰ Since the pickle data format is actually a tiny stack-oriented programming language, and some freedom is taken in the encodings of certain objects, it is possible that the two modules produce different data streams for the same input objects. However it is guaranteed that they will always be able to read each other's data streams.

(continued from previous page)

```
>>> p = pickle.dumps(c)
pickling a C instance...
```

11.4 `shelve` — Python object persistence

Source code: [Lib/shelve.py](#)

A “shelf” is a persistent, dictionary-like object. The difference with “dbm” databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects — anything that the `pickle` module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open(filename, flag='c', protocol=None, writeback=False)`

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of `anydbm.open()`.

By default, version 0 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Changed in version 2.3: The *protocol* parameter was added.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see [Example](#)). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on `sync()` and `close()`; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

Like file objects, shelf objects should be closed explicitly to ensure that the persistent data is flushed to disk.

Warning: Because the `shelve` module is backed by `pickle`, it is insecure to load a shelf from an untrusted source. Like with `pickle`, loading a shelf can execute arbitrary code.

Shelf objects support most of the methods supported by dictionaries. This eases the transition from dictionary based scripts to those requiring persistent storage.

Note, the Python 3 transition methods (`viewkeys()`, `viewvalues()`, and `viewitems()`) are not supported.

Two additional methods are supported:

`Shelf.sync()`

Write back all entries in the cache if the shelf was opened with *writeback* set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with `close()`.

`Shelf.close()`

Synchronize and close the persistent *dict* object. Operations on a closed shelf will fail with a `ValueError`.

See also:

[Persistent dictionary recipe](#) with widely supported storage formats and having the speed of native dictionaries.

11.4.1 Restrictions

- The choice of which database package will be used (such as *dbm*, *gdbm* or *bsddb*) depends on which interface is available. Therefore it is not safe to open the database directly using *dbm*. The database is also (unfortunately) subject to the limitations of *dbm*, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The *shelve* module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.

class *shelve.Shelf* (*dict*, *protocol=None*, *writeback=False*)

A subclass of *UserDict.DictMixin* which stores pickled values in the *dict* object.

By default, version 0 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the *pickle* documentation for a discussion of the pickle protocols.

Changed in version 2.3: The *protocol* parameter was added.

If the *writeback* parameter is *True*, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

class *shelve.BsddbShelf* (*dict*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which exposes *first()*, *next()*, *previous()*, *last()* and *set_location()* which are available in the *bsddb* module but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of *bsddb.hashopen()*, *bsddb.btopen()* or *bsddb.rnopen()*. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

class *shelve.DbfilenameShelf* (*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which accepts a *filename* instead of a dict-like object. The underlying file will be opened using *anydbm.open()*. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the *open()* function. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

11.4.2 Example

To summarize the interface (key is a string, data is an arbitrary object):

```
import shelve

d = shelve.open(filename) # open -- file may get suffix added by low-level
                           # library

d[key] = data             # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]             # retrieve a COPY of data at key (raise KeyError if no
                           # such key)
del d[key]                # delete data stored at key (raises KeyError
                           # if no such key)
flag = d.has_key(key)     # true if the key exists
klist = d.keys()          # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
```

(continues on next page)

(continued from previous page)

```
d['xx'] = range(4)  # this works as expected, but...
d['xx'].append(5)   # *this doesn't!* -- d['xx'] is STILL range(4)!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']      # extracts the copy
temp.append(5)      # mutates the copy
d['xx'] = temp      # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()          # close it
```

11.5 marshal — Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).¹

This is not a general “persistence” module. For general persistence and transfer of Python objects through RPC calls, see the modules *pickle* and *shelve*. The *marshal* module exists mainly to support reading and writing the “pseudo-compiled” code for Python modules of *.pyc* files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you’re serializing and de-serializing Python objects, use the *pickle* module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

Warning: The *marshal* module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, long integers, floating point numbers, complex numbers, strings, Unicode objects, tuples, lists, sets, frozensets, dictionaries, and code

¹ The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term “marshalling” for shipping of data around in a self-contained form. Strictly speaking, “to marshal” means to convert some data from internal to external form (in an RPC buffer for instance) and “unmarshalling” for the reverse process.

objects, where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported; and recursive lists, sets and dictionaries should not be written (they will cause infinite loops). The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled.

Warning: On machines where C's `long int` type has more than 32 bits (such as the DEC Alpha), it is possible to create plain Python integers that are longer than 32 bits. If such an integer is marshalled and read back in on a machine where C's `long int` type has only 32 bits, a Python long integer object is returned instead. While of a different type, the numeric value is the same. (This behavior is new in Python 2.2. In earlier versions, all but the least-significant 32 bits of the value were lost, and a warning message was printed.)

There are functions that read/write files as well as functions operating on strings.

The module defines these functions:

`marshal.dump(value, file[, version])`

Write the value on the open file. The value must be a supported type. The file must be an open file object such as `sys.stdout` or returned by `open()` or `os.popen()`. It may not be a wrapper such as `TemporaryFile` on Windows. It must be opened in binary mode ('wb' or 'w+b').

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised — but garbage data will also be written to the file. The object will not be properly read back by `load()`.

New in version 2.4: The *version* argument indicates the data format that `dump` should use (see below).

`marshal.load(file)`

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. The file must be an open file object opened in binary mode ('rb' or 'r+b').

Note: If an object containing an unsupported type was marshalled with `dump()`, `load()` will substitute *None* for the unmarshallable type.

`marshal.dumps(value[, version])`

Return the string that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type.

New in version 2.4: The *version* argument indicates the data format that `dumps` should use (see below).

`marshal.loads(string)`

Convert the string to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Extra characters in the string are ignored.

In addition, the following constants are defined:

`marshal.version`

Indicates the format that the module uses. Version 0 is the historical format, version 1 (added in Python 2.4) shares interned strings and version 2 (added in Python 2.5) uses a binary format for floating point numbers. The current version is 2.

New in version 2.4.

11.6 anydbm — Generic access to DBM-style databases

Note: The `anydbm` module has been renamed to `dbm` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

`anydbm` is a generic interface to variants of the DBM database — `dbhash` (requires `bsddb`), `gdbm`, or `dbm`. If none of these modules is installed, the slow-but-simple implementation in module `dumbdbm` will be used.

`anydbm.open(filename[, flag[, mode]])`

Open the database file `filename` and return a corresponding object.

If the database file already exists, the `whichdb` module is used to determine its type and the appropriate module is used; if it does not exist, the first module listed above that can be imported is used.

The optional `flag` argument must be one of these values:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

If not specified, the default value is 'r'.

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing `umask`).

exception `anydbm.error`

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named `anydbm.error` as the first item — the latter is used when `anydbm.error` is raised.

The object returned by `open()` supports most of the same functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `has_key()` and `keys()` methods are available. Keys and values must always be strings.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import anydbm

# Open database, creating it if necessary.
db = anydbm.open('cache', 'c')

# Record some values
db['www.python.org'] = 'Python Website'
db['www.cnn.com'] = 'Cable News Network'

# Loop through contents. Other dictionary methods
# such as .keys(), .values() also work.
for k, v in db.iteritems():
    print k, '\t', v

# Storing a non-string key or value will raise an exception (most
# likely a TypeError).
db['www.yahoo.com'] = 4

# Close when done.
db.close()
```

In addition to the dictionary-like methods, `anydbm` objects provide the following method:

`anydbm.close()`
Close the `anydbm` database.

See also:

Module `dbhash` BSD db database interface.

Module `dbm` Standard Unix database interface.

Module `dumbdbm` Portable implementation of the `dbm` interface.

Module `gdbm` GNU database interface, based on the `dbm` interface.

Module `shelve` General object persistence built on top of the Python `dbm` interface.

Module `whichdb` Utility module used to determine the type of an existing database.

11.7 `whichdb` — Guess which DBM module created a database

Note: The `whichdb` module’s only function has been put into the `dbm` module in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

The single function in this module attempts to guess which of the several simple database modules available—`dbm`, `gdbm`, or `dbhash`—should be used to open a given file.

`whichdb.whichdb(filename)`

Returns one of the following values: `None` if the file can’t be opened because it’s unreadable or doesn’t exist; the empty string (`''`) if the file’s format can’t be guessed; or a string containing the required module name, such as `'dbm'` or `'gdbm'`.

11.8 `dbm` — Simple “database” interface

Note: The `dbm` module has been renamed to `dbm.ndbm` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

The `dbm` module provides an interface to the Unix “(n)dbm” library. Dbm objects behave like mappings (dictionaries), except that keys and values are always strings. Printing a dbm object doesn’t print the keys and values, and the `items()` and `values()` methods are not supported.

This module can be used with the “classic” `ndbm` interface, the BSD DB compatibility interface, or the GNU GDBM compatibility interface. On Unix, the **configure** script will attempt to locate the appropriate header file to simplify building this module.

The module defines the following:

exception `dbm.error`

Raised on dbm-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.library`

Name of the `ndbm` implementation library used.

`dbm.open(filename[, flag[, mode]])`

Open a dbm database and return a dbm object. The *filename* argument is the name of the database file (without the `.dir` or `.pag` extensions; note that the BSD DB implementation of the interface will append the extension `.db` and only create one file).

The optional *flag* argument must be one of these values:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing `umask`).

In addition to the dictionary-like methods, dbm objects provide the following method:

`dbm.close()`

Close the dbm database.

See also:

Module *anydbm* Generic interface to dbm-style databases.

Module *gdbm* Similar interface to the GNU GDBM library.

Module *whichdb* Utility module used to determine the type of an existing database.

11.9 gdbm — GNU's reinterpretation of dbm

Note: The *gdbm* module has been renamed to `dbm.gnu` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

This module is quite similar to the *dbm* module, but uses *gdbm* instead to provide some additional functionality. Please note that the file formats created by *gdbm* and *dbm* are incompatible.

The *gdbm* module provides an interface to the GNU DBM library. *gdbm* objects behave like mappings (dictionaries), except that keys and values are always strings. Printing a *gdbm* object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

The module defines the following constant and functions:

exception `gdbm.error`

Raised on *gdbm*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

`gdbm.open(filename[, flag[, mode]])`

Open a *gdbm* database and return a *gdbm* object. The *filename* argument is the name of the database file.

The optional *flag* argument can be:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

The following additional characters may be appended to the flag to control how the database is opened:

| Value | Meaning |
|-------|---|
| 'f' | Open the database in fast mode. Writes to the database will not be synchronized. |
| 's' | Synchronized mode. This will cause changes to the database to be immediately written to the file. |
| 'u' | Do not lock database. |

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception `error` is raised if an invalid flag is specified.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0666`.

In addition to the dictionary-like methods, `gdbm` objects have the following methods:

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the `nextkey()` method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows *key* in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k != None:
    print k
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

Close the `gdbm` database.

See also:

Module *anydbm* Generic interface to dbm-style databases.

Module *whichdb* Utility module used to determine the type of an existing database.

11.10 dbhash — DBM-style interface to the BSD database library

Deprecated since version 2.6: The `dbhash` module has been removed in Python 3.

The `dbhash` module provides a function to open databases using the BSD `db` library. This module mirrors the interface of the other Python database modules that provide access to DBM-style databases. The `bsddb` module is required to use `dbhash`.

This module provides an exception and a function:

exception `dbhash.error`

Exception raised on database errors other than `KeyError`. It is a synonym for `bsddb.error`.

`dbhash.open(path[, flag[, mode]])`

Open a `db` database and return the database object. The `path` argument is the name of the database file.

The `flag` argument can be:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

For platforms on which the BSD `db` library supports locking, an `'l'` can be appended to indicate that locking should be used.

The optional `mode` parameter is used to indicate the Unix permission bits that should be set if a new database must be created; this will be masked by the current `umask` value for the process.

See also:

Module `anydbm` Generic interface to dbm-style databases.

Module `bsddb` Lower-level interface to the BSD `db` library.

Module `whichdb` Utility module used to determine the type of an existing database.

11.10.1 Database Objects

The database objects returned by `open()` provide the methods common to all the DBM-style databases and mapping objects. The following methods are available in addition to the standard methods.

`dbhash.first()`

It's possible to loop over every key/value pair in the database using this method and the `next()` method. The traversal is ordered by the databases internal hash values, and won't be sorted by the key values. This method returns the starting key.

`dbhash.last()`

Return the last key/value pair in a database traversal. This may be used to begin a reverse-order traversal; see `previous()`.

`dbhash.next()`

Returns the key next key/value pair in a database traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
print db.first()
for i in xrange(1, len(db)):
    print db.next()
```

`dbhash.previous()`

Returns the previous key/value pair in a forward-traversal of the database. In conjunction with `last()`, this may be used to implement a reverse-order traversal.

`dbhash.sync()`

This method forces any unwritten data to be written to the disk.

11.11 bsddb — Interface to Berkeley DB library

Deprecated since version 2.6: The *bsddb* module has been removed in Python 3.

The *bsddb* module provides an interface to the Berkeley DB library. Users can create hash, btree or record based library files using the appropriate open call. Bsddb objects behave generally like dictionaries. Keys and values must be strings, however, so to use other objects as keys or to store other kinds of objects the user must serialize them somehow, typically using *marshal.dumps()* or *pickle.dumps()*.

The *bsddb* module requires a Berkeley DB library version from 4.0 thru 4.7.

See also:

<http://www.jcea.es/programacion/pybsddb.htm> The website with documentation for the *bsddb.db* Python Berkeley DB interface that closely mirrors the object oriented interface provided in Berkeley DB 4.x itself.

<http://www.oracle.com/database/berkeley-db/> The Berkeley DB library.

A more modern DB, DBEnv and DBSequence object interface is available in the *bsddb.db* module which closely matches the Berkeley DB C API documented at the above URLs. Additional features provided by the *bsddb.db* API include fine tuning, transactions, logging, and multiprocess concurrent database access.

The following is a description of the legacy *bsddb* interface compatible with the old Python *bsddb* module. Starting in Python 2.5 this interface should be safe for multithreaded access. The *bsddb.db* API is recommended for threading users as it provides better control.

The *bsddb* module defines the following functions that create objects that access the appropriate type of Berkeley DB file. The first two arguments of each function are the same. For ease of portability, only the first two arguments should be used in most instances.

bsddb.hashopen (*filename*[, *flag*[, *mode*[, *pgsize*[, *ffactor*[, *nelem*[, *cachesize*[, *lorder*[, *hflags*]]]]]]]]]]]])

Open the hash format file named *filename*. Files never intended to be preserved on disk may be created by passing *None* as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level *dbopen()* function. Consult the Berkeley DB documentation for their use and interpretation.

bsddb.btopen (*filename*[, *flag*[, *mode*[, *btflags*[, *cachesize*[, *maxkeypage*[, *minkeypage*[, *pgsize*[, *lorder*]]]]]]]]]]]])

Open the btree format file named *filename*. Files never intended to be preserved on disk may be created by passing *None* as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level *dbopen* function. Consult the Berkeley DB documentation for their use and interpretation.

bsddb.rnopen (*filename*[, *flag*[, *mode*[, *rnflags*[, *cachesize*[, *pgsize*[, *lorder*[, *rlen*[, *delim*[, *source*[, *pad*]]]]]]]]]]]])

Open a DB record format file named *filename*. Files never intended to be preserved on disk may be created by passing *None* as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level *dbopen* function. Consult the Berkeley DB documentation for their use and interpretation.

Note: Beginning in 2.3 some Unix versions of Python may have a *bsddb185* module. This is present *only* to allow

backwards compatibility with systems which ship with the old Berkeley DB 1.85 database library. The `bsddb185` module should never be used directly in new code. The module has been removed in Python 3. If you find you still need it look in PyPI.

Module `dbhash` DBM-style interface to the `bsddb`

11.11.1 Hash, BTree and Record Objects

Once instantiated, hash, btree and record objects support the same methods as dictionaries. In addition, they support the methods listed below.

Changed in version 2.3.1: Added dictionary methods.

`bsddbobject.close()`

Close the underlying file. The object can no longer be accessed. Since there is no open `open()` method for these objects, to open the file again a new `bsddb` module open function must be called.

`bsddbobject.keys()`

Return the list of keys contained in the DB file. The order of the list is unspecified and should not be relied on. In particular, the order of the list returned is different for different file formats.

`bsddbobject.has_key(key)`

Return 1 if the DB file contains the argument as a key.

`bsddbobject.set_location(key)`

Set the cursor to the item indicated by `key` and return a tuple containing the key and its value. For binary tree databases (opened using `btopen()`), if `key` does not actually exist in the database, the cursor will point to the next item in sorted order and return that key and value. For other databases, `KeyError` will be raised if `key` is not found in the database.

`bsddbobject.first()`

Set the cursor to the first item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases. This method raises `bsddb.error` if the database is empty.

`bsddbobject.next()`

Set the cursor to the next item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases.

`bsddbobject.previous()`

Set the cursor to the previous item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases. This is not supported on hashtable databases (those opened with `hashopen()`).

`bsddbobject.last()`

Set the cursor to the last item in the DB file and return it. The order of keys in the file is unspecified. This is not supported on hashtable databases (those opened with `hashopen()`). This method raises `bsddb.error` if the database is empty.

`bsddbobject.sync()`

Synchronize the database on disk.

Example:

```
>>> import bsddb
>>> db = bsddb.btopen('spam.db', 'c')
>>> for i in range(10): db['%d%i' % i] = '%d' % (i*i)
...
```

(continues on next page)

(continued from previous page)

```
>>> db['3']
'9'
>>> db.keys()
['0', '1', '2', '3', '4', '5', '6', '7', '8', '9']
>>> db.first()
('0', '0')
>>> db.next()
('1', '1')
>>> db.last()
('9', '81')
>>> db.set_location('2')
('2', '4')
>>> db.previous()
('1', '1')
>>> for k, v in db.iteritems():
...     print k, v
0 0
1 1
2 4
3 9
4 16
5 25
6 36
7 49
8 64
9 81
>>> '8' in db
True
>>> db.sync()
0
```

11.12 dumbdbm — Portable DBM implementation

Note: The `dumbdbm` module has been renamed to `dbm.dumb` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

Note: The `dumbdbm` module is intended as a last resort fallback for the `anydbm` module when no more robust module is available. The `dumbdbm` module is not written for speed and is not nearly as heavily used as the other database modules.

The `dumbdbm` module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as `gdbm` and `bsddb`, no external library is required. As with other persistent mappings, the keys and values must always be strings.

The module defines the following:

exception `dumbdbm.error`

Raised on dumbdbm-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dumbdbm.open(filename[, flag[, mode]])`

Open a dumbdbm database and return a dumbdbm object. The *filename* argument is the basename of the database

file (without any specific extensions). When a dumbdbm database is created, files with `.dat` and `.dir` extensions are created.

The optional *flag* argument is currently ignored; the database is always opened for update, and will be created if it does not exist.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing umask).

Changed in version 2.2: The *mode* argument was ignored in earlier versions.

In addition to the dictionary-like methods, dumbdbm objects provide the following method:

```
dumbdbm.close()
```

Close the dumbdbm database.

See also:

Module *anydbm* Generic interface to dbm-style databases.

Module *gdbm* Similar interface to the GNU GDBM library.

Module *shelve* Persistence module which stores non-string data.

Module *whichdb* Utility module used to determine the type of an existing database.

11.12.1 Dumbdbm Objects

In addition to the methods provided by the *UserDict.DictMixin* class, dumbdbm objects provide the following methods.

```
dumbdbm.sync()
```

Synchronize the on-disk directory and data files. This method is called by the *sync()* method of *Shelve* objects.

11.13 sqlite3 — DB-API 2.0 interface for SQLite databases

New in version 2.5.

SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The sqlite3 module was written by Gerhard Häring. It provides a SQL interface compliant with the DB-API 2.0 specification described by [PEP 249](#).

To use the module, you must first create a *Connection* object that represents the database. Here the data will be stored in the `example.db` file:

```
import sqlite3
conn = sqlite3.connect('example.db')
```

You can also supply the special name `:memory:` to create a database in RAM.

Once you have a *Connection*, you can create a *Cursor* object and call its *execute()* method to perform SQL commands:

```
c = conn.cursor()

# Create table
c.execute('''CREATE TABLE stocks
            (date text, trans text, symbol text, qty real, price real)''')

# Insert a row of data
c.execute("INSERT INTO stocks VALUES ('2006-01-05','BUY','RHAT',100,35.14)")

# Save (commit) the changes
conn.commit()

# We can also close the connection if we are done with it.
# Just be sure any changes have been committed or they will be lost.
conn.close()
```

The data you've saved is persistent and is available in subsequent sessions:

```
import sqlite3
conn = sqlite3.connect('example.db')
c = conn.cursor()
```

Usually your SQL operations will need to use values from Python variables. You shouldn't assemble your query using Python's string operations because doing so is insecure; it makes your program vulnerable to an SQL injection attack (see <https://xkcd.com/327/> for humorous example of what can go wrong).

Instead, use the DB-API's parameter substitution. Put `?` as a placeholder wherever you want to use a value, and then provide a tuple of values as the second argument to the cursor's `execute()` method. (Other database modules may use a different placeholder, such as `%s` or `:1.`) For example:

```
# Never do this -- insecure!
symbol = 'RHAT'
c.execute("SELECT * FROM stocks WHERE symbol = '%s'" % symbol)

# Do this instead
t = ('RHAT',)
c.execute('SELECT * FROM stocks WHERE symbol=?', t)
print c.fetchone()

# Larger example that inserts many records at a time
purchases = [('2006-03-28', 'BUY', 'IBM', 1000, 45.00),
              ('2006-04-05', 'BUY', 'MSFT', 1000, 72.00),
              ('2006-04-06', 'SELL', 'IBM', 500, 53.00),
              ]
c.executemany('INSERT INTO stocks VALUES (?, ?, ?, ?, ?)', purchases)
```

To retrieve data after executing a SELECT statement, you can either treat the cursor as an *iterator*, call the cursor's `fetchone()` method to retrieve a single matching row, or call `fetchall()` to get a list of the matching rows.

This example uses the iterator form:

```
>>> for row in c.execute('SELECT * FROM stocks ORDER BY price'):
    print row

(u'2006-01-05', u'BUY', u'RHAT', 100, 35.14)
(u'2006-03-28', u'BUY', u'IBM', 1000, 45.0)
(u'2006-04-06', u'SELL', u'IBM', 500, 53.0)
(u'2006-04-05', u'BUY', u'MSFT', 1000, 72.0)
```

11.13.1 Module functions and constants

`sqlite3.version`

The version number of this module, as a string. This is not the version of the SQLite library.

`sqlite3.version_info`

The version number of this module, as a tuple of integers. This is not the version of the SQLite library.

`sqlite3.sqlite_version`

The version number of the run-time SQLite library, as a string.

`sqlite3.sqlite_version_info`

The version number of the run-time SQLite library, as a tuple of integers.

`sqlite3.PARSE_DECLTYPES`

This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting it makes the *sqlite3* module parse the declared type for each column it returns. It will parse out the first word of the declared type, i. e. for “integer primary key”, it will parse out “integer”, or for “number(10)” it will parse out “number”. Then for that column, it will look into the converters dictionary and use the converter function registered for that type there.

`sqlite3.PARSE_COLNAMES`

This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting this makes the SQLite interface parse the column name for each column it returns. It will look for a string formed [mytype] in there, and then decide that ‘mytype’ is the type of the column. It will try to find an entry of ‘mytype’ in the converters dictionary and then use the converter function found there to return the value. The column name found in *Cursor.description* is only the first word of the column name, i. e. if you use something like ‘as “x [datetime]”’ in your SQL, then we will parse out everything until the first blank for the column name: the column name would simply be “x”.

`sqlite3.connect(database[, timeout, detect_types, isolation_level, check_same_thread, factory, cached_statements])`

Opens a connection to the SQLite database file *database*. You can use “:memory:” to open a database connection to a database that resides in RAM instead of on disk.

When a database is accessed by multiple connections, and one of the processes modifies the database, the SQLite database is locked until that transaction is committed. The *timeout* parameter specifies how long the connection should wait for the lock to go away until raising an exception. The default for the timeout parameter is 5.0 (five seconds).

For the *isolation_level* parameter, please see the *Connection.isolation_level* property of *Connection* objects.

SQLite natively supports only the types TEXT, INTEGER, REAL, BLOB and NULL. If you want to use other types you must add support for them yourself. The *detect_types* parameter and the using custom **converters** registered with the module-level *register_converter()* function allow you to easily do that.

`detect_types` defaults to 0 (i. e. off, no type detection), you can set it to any combination of `PARSE_DECLTYPES` and `PARSE_COLNAMES` to turn type detection on.

By default, the `sqlite3` module uses its `Connection` class for the connect call. You can, however, subclass the `Connection` class and make `connect()` use your class instead by providing your class for the `factory` parameter.

Consult the section *SQLite and Python types* of this manual for details.

The `sqlite3` module internally uses a statement cache to avoid SQL parsing overhead. If you want to explicitly set the number of statements that are cached for the connection, you can set the `cached_statements` parameter. The currently implemented default is to cache 100 statements.

`sqlite3.register_converter(typename, callable)`

Registers a callable to convert a bytestring from the database into a custom Python type. The callable will be invoked for all database values that are of the type *typename*. Confer the parameter `detect_types` of the `connect()` function for how the type detection works. Note that *typename* and the name of the type in your query are matched in case-insensitive manner.

`sqlite3.register_adapter(type, callable)`

Registers a callable to convert the custom Python type *type* into one of SQLite's supported types. The callable *callable* accepts as single parameter the Python value, and must return a value of the following types: int, long, float, str (UTF-8 encoded), unicode or buffer.

`sqlite3.complete_statement(sql)`

Returns `True` if the string *sql* contains one or more complete SQL statements terminated by semicolons. It does not verify that the SQL is syntactically correct, only that there are no unclosed string literals and the statement is terminated by a semicolon.

This can be used to build a shell for SQLite, as in the following example:

```
# A minimal SQLite shell for experiments

import sqlite3

con = sqlite3.connect(":memory:")
con.isolation_level = None
cur = con.cursor()

buffer = ""

print "Enter your SQL commands to execute in sqlite3."
print "Enter a blank line to exit."

while True:
    line = raw_input()
    if line == "":
        break
    buffer += line
    if sqlite3.complete_statement(buffer):
        try:
            buffer = buffer.strip()
            cur.execute(buffer)

            if buffer.lstrip().upper().startswith("SELECT"):
                print cur.fetchall()
        except sqlite3.Error as e:
            print "An error occurred:", e.args[0]
        buffer = ""
```

(continues on next page)

(continued from previous page)

```
con.close()
```

`sqlite3.enable_callback_tracebacks(flag)`

By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use `False` to disable the feature again.

11.13.2 Connection Objects

class `sqlite3.Connection`

A SQLite database connection has the following attributes and methods:

isolation_level

Get or set the current isolation level. *None* for autocommit mode or one of “DEFERRED”, “IMMEDIATE” or “EXCLUSIVE”. See section [Controlling Transactions](#) for a more detailed explanation.

cursor (*factory=Cursor*)

The cursor method accepts a single optional parameter *factory*. If supplied, this must be a callable returning an instance of *Cursor* or its subclasses.

commit()

This method commits the current transaction. If you don’t call this method, anything you did since the last call to `commit()` is not visible from other database connections. If you wonder why you don’t see the data you’ve written to the database, please check you didn’t forget to call this method.

rollback()

This method rolls back any changes to the database since the last call to `commit()`.

close()

This closes the database connection. Note that this does not automatically call `commit()`. If you just close your database connection without calling `commit()` first, your changes will be lost!

execute (*sql[, parameters]*)

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor’s *execute* method with the parameters given.

executemany (*sql[, parameters]*)

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor’s *executemany* method with the parameters given.

executescript (*sql_script*)

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor’s *executescript* method with the parameters given.

create_function (*name, num_params, func*)

Creates a user-defined function that you can later use from within SQL statements under the function name *name*. *num_params* is the number of parameters the function accepts, and *func* is a Python callable that is called as the SQL function.

The function can return any of the types supported by SQLite: unicode, str, int, long, float, buffer and *None*.

Example:

```
import sqlite3
import md5
```

(continues on next page)

(continued from previous page)

```
def md5sum(t):
    return md5.md5(t).hexdigest()

con = sqlite3.connect(":memory:")
con.create_function("md5", 1, md5sum)
cur = con.cursor()
cur.execute("select md5(?)", ("foo",))
print cur.fetchone()[0]
```

create_aggregate (*name*, *num_params*, *aggregate_class*)

Creates a user-defined aggregate function.

The aggregate class must implement a `step` method, which accepts the number of parameters *num_params*, and a `finalize` method which will return the final result of the aggregate.

The `finalize` method can return any of the types supported by SQLite: unicode, str, int, long, float, buffer and None.

Example:

```
import sqlite3

class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.cursor()
cur.execute("create table test(i)")
cur.execute("insert into test(i) values (1)")
cur.execute("insert into test(i) values (2)")
cur.execute("select mysum(i) from test")
print cur.fetchone()[0]
```

create_collation (*name*, *callable*)

Creates a collation with the specified *name* and *callable*. The callable will be passed two string arguments. It should return -1 if the first is ordered lower than the second, 0 if they are ordered equal and 1 if the first is ordered higher than the second. Note that this controls sorting (ORDER BY in SQL) so your comparisons don't affect other SQL operations.

Note that the callable will get its parameters as Python bytestrings, which will normally be encoded in UTF-8.

The following example shows a custom collation that sorts “the wrong way”:

```
import sqlite3

def collate_reverse(string1, string2):
    return -cmp(string1, string2)

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)
```

(continues on next page)

(continued from previous page)

```

cur = con.cursor()
cur.execute("create table test(x)")
cur.executemany("insert into test(x) values (?)", [("a",), ("b",)])
cur.execute("select x from test order by x collate reverse")
for row in cur:
    print row
con.close()

```

To remove a collation, call `create_collation` with `None` as callable:

```
con.create_collation("reverse", None)
```

interrupt()

You can call this method from a different thread to abort any queries that might be executing on the connection. The query will then abort and the caller will get an exception.

set_authorizer(authorizer_callback)

This routine registers a callback. The callback is invoked for each attempt to access a column of a table in the database. The callback should return `SQLITE_OK` if access is allowed, `SQLITE_DENY` if the entire SQL statement should be aborted with an error and `SQLITE_IGNORE` if the column should be treated as a NULL value. These constants are available in the `sqlite3` module.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database (“main”, “temp”, etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

set_progress_handler(handler, n)

This routine registers a callback. The callback is invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *handler*.

New in version 2.6.

enable_load_extension(enabled)

This routine allows/disallows the SQLite engine to load SQLite extensions from shared libraries. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

Loadable extensions are disabled by default. See¹.

New in version 2.7.

```

import sqlite3

con = sqlite3.connect(":memory:")

# enable extension loading

```

(continues on next page)

¹ The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably Mac OS X) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must modify `setup.py` and remove the line that sets `SQLITE_OMIT_LOAD_EXTENSION`.

(continued from previous page)

```

con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("create virtual table recipe using fts3(name, ingredients)")
con.executescript("""
    insert into recipe (name, ingredients) values ('broccoli stew', 'broccoli_
↪peppers cheese tomatoes');
    insert into recipe (name, ingredients) values ('pumpkin stew', 'pumpkin_
↪onions garlic celery');
    insert into recipe (name, ingredients) values ('broccoli pie', 'broccoli_
↪cheese onions flour');
    insert into recipe (name, ingredients) values ('pumpkin pie', 'pumpkin_
↪sugar flour butter');
    """)
for row in con.execute("select rowid, name, ingredients from recipe where_
↪name match 'pie'"):
    print row

```

load_extension (*path*)

This routine loads a SQLite extension from a shared library. You have to enable extension loading with `enable_load_extension()` before you can use this routine.

Loadable extensions are disabled by default. See¹.

New in version 2.7.

row_factory

You can change this attribute to a callable that accepts the cursor and the original row as a tuple and will return the real result row. This way, you can implement more advanced ways of returning results, such as returning an object that can also access columns by name.

Example:

```

import sqlite3

def dict_factory(cursor, row):
    d = {}
    for idx, col in enumerate(cursor.description):
        d[col[0]] = row[idx]
    return d

con = sqlite3.connect(":memory:")
con.row_factory = dict_factory
cur = con.cursor()
cur.execute("select 1 as a")
print cur.fetchone()[ "a" ]

```

If returning a tuple doesn't suffice and you want name-based access to columns, you should consider setting `row_factory` to the highly-optimized `sqlite3.Row` type. `Row` provides both index-based and case-

insensitive name-based access to columns with almost no memory overhead. It will probably be better than your own custom dictionary-based approach or even a `db_row` based solution.

text_factory

Using this attribute you can control what objects are returned for the TEXT data type. By default, this attribute is set to `unicode` and the `sqlite3` module will return Unicode objects for TEXT. If you want to return bytestrings instead, you can set it to `str`.

For efficiency reasons, there's also a way to return Unicode objects only for non-ASCII data, and bytestrings otherwise. To activate it, set this attribute to `sqlite3.OptimizedUnicode`.

You can also set it to any other callable that accepts a single bytestring parameter and returns the resulting object.

See the following example code for illustration:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()

AUSTRIA = u"\xd6sterreich"

# by default, rows are returned as Unicode
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA

# but we can make sqlite3 always return bytestrings ...
con.text_factory = str
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is str
# the bytestrings will be encoded in UTF-8, unless you stored garbage in the
# database ...
assert row[0] == AUSTRIA.encode("utf-8")

# we can also implement a custom text_factory ...
# here we implement one that will ignore Unicode characters that cannot be
# decoded from UTF-8
con.text_factory = lambda x: unicode(x, "utf-8", "ignore")
cur.execute("select ?", ("this is latin1 and would normally create errors" +
                        u"\xe4\xf6\xfc".encode("latin1"),))
row = cur.fetchone()
assert type(row[0]) is unicode

# sqlite3 offers a built-in optimized text_factory that will return bytestring
# objects, if the data is in ASCII only, and otherwise return unicode objects
con.text_factory = sqlite3.OptimizedUnicode
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is unicode

cur.execute("select ?", ("Germany",))
row = cur.fetchone()
assert type(row[0]) is str
```

total_changes

Returns the total number of database rows that have been modified, inserted, or deleted since the database

connection was opened.

iterdump

Returns an iterator to dump the database in an SQL text format. Useful when saving an in-memory database for later restoration. This function provides the same capabilities as the `.dump` command in the **sqlite3** shell.

New in version 2.6.

Example:

```
# Convert file existing_db.db to SQL dump file dump.sql
import sqlite3, os

con = sqlite3.connect('existing_db.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
```

11.13.3 Cursor Objects

class `sqlite3.Cursor`

A *Cursor* instance has the following attributes and methods.

execute (*sql* [, *parameters*])

Executes an SQL statement. The SQL statement may be parameterized (i. e. placeholders instead of SQL literals). The *sqlite3* module supports two kinds of placeholders: question marks (qmark style) and named placeholders (named style).

Here's an example of both styles:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table people (name_last, age)")

who = "Yeltsin"
age = 72

# This is the qmark style:
cur.execute("insert into people values (?, ?)", (who, age))

# And this is the named style:
cur.execute("select * from people where name_last=:who and age=:age", {"who": who, "age": age})

print cur.fetchone()
```

execute() will only execute a single SQL statement. If you try to execute more than one statement with it, it will raise a Warning. Use *executescript()* if you want to execute multiple SQL statements with one call.

executemany (*sql*, *seq_of_parameters*)

Executes an SQL command against all parameter sequences or mappings found in the sequence *sql*. The *sqlite3* module also allows using an *iterator* yielding parameters instead of a sequence.

```

import sqlite3

class IterChars:
    def __init__(self):
        self.count = ord('a')

    def __iter__(self):
        return self

    def next(self):
        if self.count > ord('z'):
            raise StopIteration
        self.count += 1
        return (chr(self.count - 1),) # this is a 1-tuple

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

theIter = IterChars()
cur.executemany("insert into characters(c) values (?)", theIter)

cur.execute("select c from characters")
print cur.fetchall()

```

Here's a shorter example using a *generator*:

```

import sqlite3
import string

def char_generator():
    for c in string.lowercase:
        yield (c,)

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

cur.executemany("insert into characters(c) values (?)", char_generator())

cur.execute("select c from characters")
print cur.fetchall()

```

executescript (*sql_script*)

This is a nonstandard convenience method for executing multiple SQL statements at once. It issues a COMMIT statement first, then executes the SQL script it gets as a parameter.

sql_script can be a bytestring or a Unicode string.

Example:

```

import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.executescript("""
    create table person(
        firstname,

```

(continues on next page)

(continued from previous page)

```
        lastname,
        age
    );

    create table book(
        title,
        author,
        published
    );

    insert into book(title, author, published)
    values (
        'Dirk Gently''s Holistic Detective Agency',
        'Douglas Adams',
        1987
    );
    """
```

fetchone()

Fetches the next row of a query result set, returning a single sequence, or *None* when no more data is available.

fetchmany([size=cursor.arraysize])

Fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If it is not given, the cursor's *arraysize* determines the number of rows to be fetched. The method should try to fetch as many rows as indicated by the *size* parameter. If this is not possible due to the specified number of rows not being available, fewer rows may be returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the *arraysize* attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()

Fetches all (remaining) rows of a query result, returning a list. Note that the cursor's *arraysize* attribute can affect the performance of this operation. An empty list is returned when no rows are available.

rowcount

Although the *Cursor* class of the *sqlite3* module implements this attribute, the database engine's own support for the determination of "rows affected"/"rows selected" is quirky.

For *executemany()* statements, the number of modifications are summed up into *rowcount*.

As required by the Python DB API Spec, the *rowcount* attribute "is -1 in case no *executeXX()* has been performed on the cursor or the rowcount of the last operation is not determinable by the interface". This includes *SELECT* statements because we cannot determine the number of rows a query produced until all rows were fetched.

With SQLite versions before 3.6.5, *rowcount* is set to 0 if you make a *DELETE FROM table* without any condition.

lastrowid

This read-only attribute provides the rowid of the last modified row. It is only set if you issued an *INSERT* statement using the *execute()* method. For operations other than *INSERT* or when *executemany()* is called, *lastrowid* is set to *None*.

description

This read-only attribute provides the column names of the last query. To remain compatible with the Python

DB API, it returns a 7-tuple for each column where the last six items of each tuple are *None*.

It is set for `SELECT` statements without any matching rows as well.

connection

This read-only attribute provides the SQLite database *Connection* used by the *Cursor* object. A *Cursor* object created by calling `con.cursor()` will have a *connection* attribute that refers to *con*:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

11.13.4 Row Objects

class `sqlite3.Row`

A *Row* instance serves as a highly optimized *row_factory* for *Connection* objects. It tries to mimic a tuple in most of its features.

It supports mapping access by column name and index, iteration, representation, equality testing and `len()`.

If two *Row* objects have exactly the same columns and their members are equal, they compare equal.

Changed in version 2.6: Added iteration and equality (hashability).

keys()

This method returns a list of column names. Immediately after a query, it is the first member of each tuple in *Cursor.description*.

New in version 2.6.

Let's assume we initialize a table as in the example given above:

```
conn = sqlite3.connect(":memory:")
c = conn.cursor()
c.execute('''create table stocks
(date text, trans text, symbol text,
 qty real, price real)''')
c.execute("""insert into stocks
          values ('2006-01-05', 'BUY', 'RHAT', 100, 35.14) """)
conn.commit()
c.close()
```

Now we plug *Row* in:

```
>>> conn.row_factory = sqlite3.Row
>>> c = conn.cursor()
>>> c.execute('select * from stocks')
<sqlite3.Cursor object at 0x7f4e7dd8fa80>
>>> r = c.fetchone()
>>> type(r)
<type 'sqlite3.Row'>
>>> r
(u'2006-01-05', u'BUY', u'RHAT', 100.0, 35.14)
>>> len(r)
5
>>> r[2]
u'RHAT'
```

(continues on next page)

(continued from previous page)

```

>>> r.keys()
['date', 'trans', 'symbol', 'qty', 'price']
>>> r['qty']
100.0
>>> for member in r:
...     print member
...
2006-01-05
BUY
RHAT
100.0
35.14

```

11.13.5 SQLite and Python types

Introduction

SQLite natively supports the following types: NULL, INTEGER, REAL, TEXT, BLOB.

The following Python types can thus be sent to SQLite without any problem:

| Python type | SQLite type |
|---------------------------|-------------|
| <i>None</i> | NULL |
| <i>int</i> | INTEGER |
| <i>long</i> | INTEGER |
| <i>float</i> | REAL |
| <i>str</i> (UTF8-encoded) | TEXT |
| <i>unicode</i> | TEXT |
| <i>buffer</i> | BLOB |

This is how SQLite types are converted to Python types by default:

| SQLite type | Python type |
|-------------|--|
| NULL | <i>None</i> |
| INTEGER | <i>int</i> or <i>long</i> , depending on size |
| REAL | <i>float</i> |
| TEXT | depends on <i>text_factory</i> , <i>unicode</i> by default |
| BLOB | <i>buffer</i> |

The type system of the *sqlite3* module is extensible in two ways: you can store additional Python types in a SQLite database via object adaptation, and you can let the *sqlite3* module convert SQLite types to different Python types via converters.

Using adapters to store additional Python types in SQLite databases

As described before, SQLite supports only a limited set of types natively. To use other Python types with SQLite, you must **adapt** them to one of the *sqlite3* module's supported types for SQLite: one of *NoneType*, *int*, *long*, *float*, *str*, *unicode*, *buffer*.

There are two ways to enable the *sqlite3* module to adapt a custom Python type to one of the supported ones.

Letting your object adapt itself

This is a good approach if you write the class yourself. Let's suppose you have a class like this:

```
class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y
```

Now you want to store the point in a single SQLite column. First you'll have to choose one of the supported types first to be used for representing the point. Let's just use str and separate the coordinates using a semicolon. Then you need to give your class a method `__conform__(self, protocol)` which must return the converted value. The parameter *protocol* will be `PrepareProtocol`.

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return "%f;%f" % (self.x, self.y)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print cur.fetchone()[0]
```

Registering an adapter callable

The other possibility is to create a function that converts the type to the string representation and register the function with `register_adapter()`.

Note: The type/class to adapt must be a *new-style class*, i. e. it must have *object* as one of its bases.

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print cur.fetchone()[0]
```

The `sqlite3` module has two default adapters for Python's built-in `datetime.date` and `datetime.datetime` types. Now let's suppose we want to store `datetime.datetime` objects not in ISO representation, but as a Unix timestamp.

```
import sqlite3
import datetime, time

def adapt_datetime(ts):
    return time.mktime(ts.timetuple())

sqlite3.register_adapter(datetime.datetime, adapt_datetime)

con = sqlite3.connect(":memory:")
cur = con.cursor()

now = datetime.datetime.now()
cur.execute("select ?", (now,))
print cur.fetchone()[0]
```

Converting SQLite values to custom Python types

Writing an adapter lets you send custom Python types to SQLite. But to make it really useful we need to make the Python to SQLite to Python roundtrip work.

Enter converters.

Let's go back to the `Point` class. We stored the `x` and `y` coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

Note: Converter functions **always** get called with a string, no matter under which data type you sent the value to SQLite.

```
def convert_point(s):
    x, y = map(float, s.split(";"))
    return Point(x, y)
```

Now you need to make the `sqlite3` module know that what you select from the database is actually a point. There are two ways of doing this:

- Implicitly via the declared type
- Explicitly via the column name

Both ways are described in section *Module functions and constants*, in the entries for the constants `PARSE_DECLTYPES` and `PARSE_COLNAMES`.

The following example illustrates both approaches.

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return "({f};{f})".format(self.x, self.y)
```

(continues on next page)

(continued from previous page)

```

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

def convert_point(s):
    x, y = map(float, s.split(";"))
    return Point(x, y)

# Register the adapter
sqlite3.register_adapter(Point, adapt_point)

# Register the converter
sqlite3.register_converter("point", convert_point)

p = Point(4.0, -3.2)

#####
# 1) Using declared types
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(p point)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute("select p from test")
print "with declared types:", cur.fetchone()[0]
cur.close()
con.close()

#####
# 1) Using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(p)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute('select p as "p [point]" from test')
print "with column names:", cur.fetchone()[0]
cur.close()
con.close()

```

Default adapters and converters

There are default adapters for the date and datetime types in the datetime module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name “date” for `datetime.date` and under the name “timestamp” for `datetime.datetime`.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```

import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES|sqlite3.PARSE_
→COLNAMES)

```

(continues on next page)

(continued from previous page)

```

cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print today, "=>", row[0], type(row[0])
print now, "=>", row[1], type(row[1])

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"
↪')
row = cur.fetchone()
print "current_date", row[0], type(row[0])
print "current_timestamp", row[1], type(row[1])

```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

11.13.6 Controlling Transactions

By default, the `sqlite3` module opens transactions implicitly before a Data Modification Language (DML) statement (i.e. INSERT/UPDATE/DELETE/REPLACE), and commits transactions implicitly before a non-DML, non-query statement (i. e. anything other than SELECT or the aforementioned).

So if you are within a transaction and issue a command like CREATE TABLE ..., VACUUM, PRAGMA, the `sqlite3` module will commit implicitly before executing that command. There are two reasons for doing that. The first is that some of these commands don't work within transactions. The other reason is that `sqlite3` needs to keep track of the transaction state (if a transaction is active or not).

You can control which kind of BEGIN statements `sqlite3` implicitly executes (or none at all) via the `isolation_level` parameter to the `connect()` call, or via the `isolation_level` property of connections.

If you want **autocommit mode**, then set `isolation_level` to `None`.

Otherwise leave it at its default, which will result in a plain "BEGIN" statement, or set it to one of SQLite's supported isolation levels: "DEFERRED", "IMMEDIATE" or "EXCLUSIVE".

11.13.7 Using `sqlite3` efficiently

Using shortcut methods

Using the nonstandard `execute()`, `executemany()` and `executescript()` methods of the `Connection` object, your code can be written more concisely because you don't have to create the (often superfluous) `Cursor` objects explicitly. Instead, the `Cursor` objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a SELECT statement and iterate over it directly using only a single call on the `Connection` object.

```

import sqlite3

persons = [
    ("Hugo", "Boss"),
    ("Calvin", "Klein")
]

```

(continues on next page)

(continued from previous page)

```

    ]

con = sqlite3.connect(":memory:")

# Create the table
con.execute("create table person(firstname, lastname)")

# Fill the table
con.executemany("insert into person(firstname, lastname) values (?, ?)", persons)

# Print the table contents
for row in con.execute("select firstname, lastname from person"):
    print row

print "I just deleted", con.execute("delete from person").rowcount, "rows"

```

Accessing columns by name instead of by index

One useful feature of the `sqlite3` module is the built-in `sqlite3.Row` class designed to be used as a row factory.

Rows wrapped with this class can be accessed both by index (like tuples) and case-insensitively by name:

```

import sqlite3

con = sqlite3.connect(":memory:")
con.row_factory = sqlite3.Row

cur = con.cursor()
cur.execute("select 'John' as name, 42 as age")
for row in cur:
    assert row[0] == row["name"]
    assert row["name"] == row["nAmE"]
    assert row[1] == row["age"]
    assert row[1] == row["AgE"]

```

Using the connection as a context manager

New in version 2.6.

Connection objects can be used as context managers that automatically commit or rollback transactions. In the event of an exception, the transaction is rolled back; otherwise, the transaction is committed:

```

import sqlite3

con = sqlite3.connect(":memory:")
con.execute("create table person (id integer primary key, firstname varchar unique)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("insert into person(firstname) values (?)", ("Joe",))

# con.rollback() is called after the with block finishes with an exception, the
# exception is still raised and must be caught
try:

```

(continues on next page)

(continued from previous page)

```
with con:
    con.execute("insert into person(firstname) values (?)", ("Joe",))
except sqlite3.IntegrityError:
    print "couldn't add Joe twice"
```

11.13.8 Common issues

Multithreading

Older SQLite versions had issues with sharing connections between threads. That's why the Python module disallows sharing connections and cursors between threads. If you still try to do so, you will get an exception at runtime.

The only exception is calling the `interrupt()` method, which only makes sense to call from a different thread.

DATA COMPRESSION AND ARCHIVING

The modules described in this chapter support data compression with the `zlib`, `gzip`, and `bzip2` algorithms, and the creation of ZIP- and tar-format archives. See also *Archiving operations* provided by the `shutil` module.

12.1 `zlib` — Compression compatible with `gzip`

For applications that require data compression, the functions in this module allow compression and decompression, using the `zlib` library. The `zlib` library has its own home page at <http://www.zlib.net>. There are known incompatibilities between the Python module and versions of the `zlib` library earlier than 1.1.3; 1.1.3 has a security vulnerability, so we recommend using 1.1.4 or later.

`zlib`'s functions have many options and often need to be used in a particular order. This documentation doesn't attempt to cover all of the permutations; consult the `zlib` manual at <http://www.zlib.net/manual.html> for authoritative information.

For reading and writing `.gz` files see the `gzip` module.

The available exception and functions in this module are:

exception `zlib.error`

Exception raised on compression and decompression errors.

`zlib.adler32` (*data* [, *value*])

Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) If *value* is present, it is used as the starting value of the checksum; otherwise, a fixed default value is used. This allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

This function always returns an integer object.

Note: To generate the same numeric value across all Python versions and platforms use `adler32(data) & 0xffffffff`. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

Changed in version 2.6: The return value is in the range `[-2**31, 2**31-1]` regardless of platform. In older versions the value is signed on some platforms and unsigned on others.

Changed in version 3.0: The return value is unsigned and in the range `[0, 2**32-1]` regardless of platform.

`zlib.compress` (*string* [, *level*])

Compresses the data in *string*, returning a string contained compressed data. *level* is an integer from 0 to 9 controlling the level of compression; 1 is fastest and produces the least compression, 9 is slowest and produces the most. 0 is no compression. The default value is 6. Raises the `error` exception if any error occurs.

`zlib.compressobj([level[, method[, wbits[, memlevel[, strategy]]]])`

Returns a compression object, to be used for compressing data streams that won't fit into memory at once. *level* is an integer from 0 to 9 or -1, controlling the level of compression; 1 is fastest and produces the least compression, 9 is slowest and produces the most. 0 is no compression. The default value is -1 (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

method is the compression algorithm. Currently, the only supported value is DEFLATED.

The *wbits* argument controls the size of the history buffer (or the “window size”) used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values. The default is 15.

- +9 to +15: The base-two logarithm of the window size, which therefore ranges between 512 and 32768. Larger values produce better compression at the expense of greater memory usage. The resulting output will include a zlib-specific header and trailer.
- -9 to -15: Uses the absolute value of *wbits* as the window size logarithm, while producing a raw output stream with no header or trailing checksum.
- +25 to +31 = 16 + (9 to 15): Uses the low 4 bits of the value as the window size logarithm, while including a basic **gzip** header and trailing checksum in the output.

memlevel controls the amount of memory used for internal compression state. Valid values range from 1 to 9. Higher values using more memory, but are faster and produce smaller output. The default is 8.

strategy is used to tune the compression algorithm. Possible values are Z_DEFAULT_STRATEGY, Z_FILTERED, and Z_HUFFMAN_ONLY. The default is Z_DEFAULT_STRATEGY.

`zlib.crc32(data[, value])`

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. If *value* is present, it is used as the starting value of the checksum; otherwise, a fixed default value is used. This allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

This function always returns an integer object.

Note: To generate the same numeric value across all Python versions and platforms use `crc32(data) & 0xffffffff`. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

Changed in version 2.6: The return value is in the range `[-2**31, 2**31-1]` regardless of platform. In older versions the value would be signed on some platforms and unsigned on others.

Changed in version 3.0: The return value is unsigned and in the range `[0, 2**32-1]` regardless of platform.

`zlib.decompress(string[, wbits[, bufsize]])`

Decompresses the data in *string*, returning a string containing the uncompressed data. The *wbits* parameter depends on the format of *string*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the `error` exception if any error occurs.

The *wbits* parameter controls the size of the history buffer (or “window size”), and what header and trailer format is expected. It is similar to the parameter for `compressobj()`, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- -8 to -15: Uses the absolute value of *wbits* as the window size logarithm. The input must be a raw stream with no header or trailer.

- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must include a gzip header and trailer.
- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an *error* exception. The default *wbits* value is 15, which corresponds to the largest window size and requires a zlib header and trailer to be included.

bufsize is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to `malloc()`. The default size is 16384.

`zlib.decompressobj([wbits])`

Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the “window size”), and what header and trailer format is expected. It has the same meaning as *described for decompress()*.

Compression objects support the following methods:

`Compress.compress(string)`

Compress *string*, returning a string containing compressed data for at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the `compress()` method. Some input may be kept in internal buffers for later processing.

`Compress.flush([mode])`

All pending input is processed, and a string containing the remaining compressed output is returned. *mode* can be selected from the constants `Z_SYNC_FLUSH`, `Z_FULL_FLUSH`, or `Z_FINISH`, defaulting to `Z_FINISH`. `Z_SYNC_FLUSH` and `Z_FULL_FLUSH` allow compressing further strings of data, while `Z_FINISH` finishes the compressed stream and prevents compressing any more data. After calling `flush()` with *mode* set to `Z_FINISH`, the `compress()` method cannot be called again; the only realistic action is to delete the object.

`Compress.copy()`

Returns a copy of the compression object. This can be used to efficiently compress a set of data that share a common initial prefix.

New in version 2.5.

Decompression objects support the following methods, and two attributes:

`Decompress.unused_data`

A string which contains any bytes past the end of the compressed data. That is, this remains "" until the last byte that contains compression data is available. If the whole string turned out to contain compressed data, this is "", the empty string.

The only way to determine where a string of compressed data ends is by actually decompressing it. This means that when compressed data is contained part of a larger file, you can only find the end of it by reading data and feeding it followed by some non-empty string into a decompression object's `decompress()` method until the `unused_data` attribute is no longer the empty string.

`Decompress.unconsumed_tail`

A string that contains any data that was not consumed by the last `decompress()` call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent `decompress()` method call in order to get correct output.

`Decompress.decompress(string[, max_length])`

Decompress *string*, returning a string containing the uncompressed data corresponding to at least part of the data

in *string*. This data should be concatenated to the output produced by any preceding calls to the `decompress()` method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max_length* is non-zero then the return value will be no longer than *max_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute `unconsumed_tail`. This string must be passed to a subsequent call to `decompress()` if decompression is to continue. If *max_length* is not supplied then the whole input is decompressed, and `unconsumed_tail` is an empty string.

`Decompress.flush([length])`

All pending input is processed, and a string containing the remaining uncompressed output is returned. After calling `flush()`, the `decompress()` method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

`Decompress.copy()`

Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

New in version 2.5.

Module `gzip` Reading and writing `gzip`-format files.

<http://www.zlib.net> The zlib library home page.

<http://www.zlib.net/manual.html> The zlib manual explains the semantics and usage of the library's many functions.

12.2 gzip — Support for gzip files

Source code: [Lib/gzip.py](#)

This module provides a simple interface to compress and decompress files just like the GNU programs `gzip` and `gunzip` would.

The data compression is provided by the `zlib` module.

The `gzip` module provides the `GzipFile` class which is modeled after Python's File Object. The `GzipFile` class reads and writes `gzip`-format files, automatically compressing or decompressing the data so that it looks like an ordinary file object.

Note that additional file formats which can be decompressed by the `gzip` and `gunzip` programs, such as those produced by `compress` and `pack`, are not supported by this module.

The module defines the following items:

`class gzip.GzipFile([filename[, mode[, compresslevel[, fileobj[, mtime]]]])`

Constructor for the `GzipFile` class, which simulates most of the methods of a file object, with the exception of the `readinto()` and `truncate()` methods. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, a `StringIO` object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the `gzip` file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, or `'wb'`, depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is `'rb'`. If not given, the `'b'` flag will be added to the mode to ensure the file is opened in binary mode for cross-platform portability.

The *compresslevel* argument is an integer from 0 to 9 controlling the level of compression; 1 is fastest and produces the least compression, and 9 is slowest and produces the most compression. 0 is no compression. The default is 9.

The *mtime* argument is an optional numeric timestamp to be written to the stream when compressing. All **gzip** compressed streams are required to contain a timestamp. If omitted or `None`, the current time is used. This module ignores the timestamp when decompressing; however, some programs, such as **gunzip**, make use of it. The format of the timestamp is the same as that of the return value of `time.time()` and of the `st_mtime` attribute of the object returned by `os.stat()`.

Calling a *GzipFile* object's `close()` method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass a *StringIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *StringIO* object's `getvalue()` method.

GzipFile supports iteration and the `with` statement.

Changed in version 2.7: Support for the `with` statement was added.

Changed in version 2.7: Support for zero-padded files was added.

New in version 2.7: The *mtime* argument.

```
gzip.open(filename[, mode[, compresslevel]])
```

This is a shorthand for `GzipFile(filename, mode, compresslevel)`. The *filename* argument is required; *mode* defaults to `'rb'` and *compresslevel* defaults to 9.

12.2.1 Examples of usage

Example of how to read a compressed file:

```
import gzip
with gzip.open('file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Example of how to create a compressed GZIP file:

```
import gzip
content = "Lots of content here"
with gzip.open('file.txt.gz', 'wb') as f:
    f.write(content)
```

Example of how to GZIP compress an existing file:

```
import gzip
import shutil
with open('file.txt', 'rb') as f_in, gzip.open('file.txt.gz', 'wb') as f_out:
    shutil.copyfileobj(f_in, f_out)
```

See also:

Module *zlib* The basic data compression module needed to support the **gzip** file format.

12.3 bz2 — Compression compatible with bzip2

New in version 2.3.

This module provides a comprehensive interface for the bz2 compression library. It implements a complete file interface, one-shot (de)compression functions, and types for sequential (de)compression.

Here is a summary of the features offered by the bz2 module:

- `BZ2File` class implements a complete file interface, including `readline()`, `readlines()`, `writelines()`, `seek()`, etc;
- `BZ2File` class implements emulated `seek()` support;
- `BZ2File` class implements universal newline support;
- `BZ2File` class offers an optimized line iteration using the readahead algorithm borrowed from file objects;
- Sequential (de)compression supported by `BZ2Compressor` and `BZ2Decompressor` classes;
- One-shot (de)compression supported by `compress()` and `decompress()` functions;
- Thread safety uses individual locking mechanism.

Note: Handling of multi-stream bzip2 files is not supported. Modules such as `bz2file` let you overcome this.

12.3.1 (De)compression of files

Handling of compressed files is offered by the `BZ2File` class.

class `bz2.BZ2File` (*filename*`[, mode``[, buffering``[, compresslevel``]]]`)

Open a bz2 file. Mode can be either 'r' or 'w', for reading (default) or writing. When opened for writing, the file will be created if it doesn't exist, and truncated otherwise. If *buffering* is given, 0 means unbuffered, and larger numbers specify the buffer size; the default is 0. If *compresslevel* is given, it must be a number between 1 and 9; the default is 9. Add a 'U' to mode to open the file for input in *universal newlines* mode. Any line ending in the input file will be seen as a '\n' in Python. Also, a file so opened gains the attribute `newlines`; the value for this attribute is one of `None` (no newline read yet), '\r', '\n', '\r\n' or a tuple containing all the newline types seen. Universal newlines are available only when reading. Instances support iteration in the same way as normal *file* instances.

`BZ2File` supports the `with` statement.

Changed in version 2.7: Support for the `with` statement was added.

Note: This class does not support input files containing multiple streams (such as those produced by the `pbzip2` tool). When reading such an input file, only the first stream will be accessible. If you require support for multi-stream files, consider using the third-party `bz2file` module (available from `PyPI`). This module provides a backport of Python 3.3's `BZ2File` class, which does support multi-stream files.

close (`()`)

Close the file. Sets data attribute `closed` to true. A closed file cannot be used for further I/O operations. `close()` may be called more than once without error.

read (`[size]`)

Read at most *size* uncompressed bytes, returned as a string. If the *size* argument is negative or omitted, read until EOF is reached.

readline (`[size]`)

Return the next line from the file, as a string, retaining newline. A non-negative *size* argument limits the maximum number of bytes to return (an incomplete line may be returned then). Return an empty string at EOF.

readlines (*[size]*)

Return a list of lines read. The optional *size* argument, if given, is an approximate bound on the total number of bytes in the lines returned.

xreadlines ()

For backward compatibility. *BZ2File* objects now include the performance optimizations previously implemented in the *xreadlines* module.

Deprecated since version 2.3: This exists only for compatibility with the method by this name on *file* objects, which is deprecated. Use *for line in file* instead.

seek (*offset*, *[whence]*)

Move to new file position. Argument *offset* is a byte count. Optional argument *whence* defaults to *os.SEEK_SET* or 0 (offset from start of file; offset should be ≥ 0); other values are *os.SEEK_CUR* or 1 (move relative to current position; offset can be positive or negative), and *os.SEEK_END* or 2 (move relative to end of file; offset is usually negative, although many platforms allow seeking beyond the end of a file).

Note that seeking of bz2 files is emulated, and depending on the parameters the operation may be extremely slow.

tell ()

Return the current file position, an integer (may be a long integer).

write (*data*)

Write string *data* to file. Note that due to buffering, *close()* may be needed before the file on disk reflects the data written.

writelines (*sequence_of_strings*)

Write the sequence of strings to the file. Note that newlines are not added. The sequence can be any iterable object producing strings. This is equivalent to calling *write()* for each string.

12.3.2 Sequential (de)compression

Sequential compression and decompression is done using the classes *BZ2Compressor* and *BZ2Decompressor*.

class *bz2.BZ2Compressor* (*[compresslevel]*)

Create a new compressor object. This object may be used to compress data sequentially. If you want to compress data in one shot, use the *compress()* function instead. The *compresslevel* parameter, if given, must be a number between 1 and 9; the default is 9.

compress (*data*)

Provide more data to the compressor object. It will return chunks of compressed data whenever possible. When you've finished providing data to compress, call the *flush()* method to finish the compression process, and return what is left in internal buffers.

flush ()

Finish the compression process and return what is left in internal buffers. You must not use the compressor object after calling this method.

class *bz2.BZ2Decompressor*

Create a new decompressor object. This object may be used to decompress data sequentially. If you want to decompress data in one shot, use the *decompress()* function instead.

decompress (*data*)

Provide more data to the decompressor object. It will return chunks of decompressed data whenever possible. If you try to decompress data after the end of stream is found, *EOFError* will be raised. If any data was found after the end of stream, it'll be ignored and saved in *unused_data* attribute.

12.3.3 One-shot (de)compression

One-shot compression and decompression is provided through the `compress()` and `decompress()` functions.

`bz2.compress(data[, compresslevel])`

Compress *data* in one shot. If you want to compress data sequentially, use an instance of `BZ2Compressor` instead. The *compresslevel* parameter, if given, must be a number between 1 and 9; the default is 9.

`bz2.decompress(data)`

Decompress *data* in one shot. If you want to decompress data sequentially, use an instance of `BZ2Decompressor` instead.

12.4 zipfile — Work with ZIP archives

New in version 1.6.

Source code: [Lib/zipfile.py](#)

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in [PKZIP Application Note](#).

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GByte in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

exception `zipfile.BadZipfile`

The error raised for bad ZIP files (old name: `zipfile.error`).

exception `zipfile.LargeZipFile`

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

class `zipfile.ZipFile`

The class for reading and writing ZIP files. See section [ZipFile Objects](#) for constructor details.

class `zipfile.PyZipFile`

Class for creating ZIP archives containing Python libraries.

class `zipfile.ZipInfo([filename[, date_time]])`

Class used to represent information about a member of an archive. Instances of this class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Most users of the `zipfile` module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section [ZipInfo Objects](#).

`zipfile.is_zipfile(filename)`

Returns True if *filename* is a valid ZIP file based on its magic number, otherwise returns False. *filename* may be a file or file-like object too.

Changed in version 2.7: Support for file and file-like objects.

`zipfile.ZIP_STORED`

The numeric constant for an uncompressed archive member.

zipfile.ZIP_DEFLATED

The numeric constant for the usual ZIP compression method. This requires the `zlib` module. No other compression methods are currently supported.

See also:

PKZIP Application Note Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

Info-ZIP Home Page Information about the Info-ZIP project's ZIP archive programs and development libraries.

12.4.1 ZipFile Objects

class `zipfile.ZipFile(file[, mode[, compression[, allowZip64]]])`

Open a ZIP file, where *file* can be either a path to a file (a string) or a file-like object. The *mode* parameter should be 'r' to read an existing file, 'w' to truncate and write a new file, or 'a' to append to an existing file. If *mode* is 'a' and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`).

Changed in version 2.6: If *mode* is 'a' and the file does not exist at all, it is created.

compression is the ZIP compression method to use when writing the archive, and should be `ZIP_STORED` or `ZIP_DEFLATED`; unrecognized values will cause `RuntimeError` to be raised. If `ZIP_DEFLATED` is specified but the `zlib` module is not available, `RuntimeError` is also raised. The default is `ZIP_STORED`. If *allowZip64* is `True` `zipfile` will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 2 GB. If it is `false` (the default) `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions. ZIP64 extensions are disabled by default because the default `zip` and `unzip` commands on Unix (the InfoZIP utilities) don't support these extensions.

Changed in version 2.7.1: If the file is created with mode 'a' or 'w' and then *closed* without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

`ZipFile` is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

New in version 2.7: Added the ability to use `ZipFile` as a context manager.

`ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

`ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member *name*. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

`ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name[, mode[, pwd]])`

Extract a member from the archive as a file-like object (`ZipExtFile`). *name* is the name of the file in the archive, or a `ZipInfo` object. The *mode* parameter, if included, must be one of the following: 'r' (the default), 'U', or

'rU'. Choosing 'U' or 'rU' will enable *universal newline* support in the read-only object. *pwd* is the password used for encrypted files. Calling *open()* on a closed *ZipFile* will raise a *RuntimeError*.

Note: The file-like object is read-only and provides the following methods: *read()*, *readline()*, *readlines()*, *__iter__()*, *next()*.

Note: If the *ZipFile* was created by passing in a file-like object as the first argument to the constructor, then the object returned by *open()* shares the *ZipFile*'s file pointer. Under these circumstances, the object returned by *open()* should not be used after any additional operations are performed on the *ZipFile* object. If the *ZipFile* was created by passing in a string (the filename) as the first argument to the constructor, then *open()* will create a new file object that will be held by the *ZipExtFile*, allowing it to operate independently of the *ZipFile*.

Note: The *open()*, *read()* and *extract()* methods can take a filename or a *ZipInfo* object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

New in version 2.6.

ZipFile.**extract** (*member* [, *path* [, *pwd*]])

Extract a member from the archive to the current working directory; *member* must be its full name or a *ZipInfo* object). Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a *ZipInfo* object. *pwd* is the password used for encrypted files.

Returns the normalized path created (a directory or new file).

New in version 2.6.

Note: If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: *///foo/bar* becomes *foo/bar* on Unix, and *C:\foo\bar* becomes *foo\bar* on Windows. And all "." components in a member filename will be removed, e.g.: *../../foo../../ba..r* becomes *foo../ba..r*. On Windows illegal characters (:, <, >, |, ", ?, and *) replaced by underscore (_).

ZipFile.**extractall** ([*path* [, *members* [, *pwd*]]])

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by *namelist()*. *pwd* is the password used for encrypted files.

Warning: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with "/" or filenames with two dots ".".

Changed in version 2.7.4: The zipfile module attempts to prevent that. See *extract()* note.

New in version 2.6.

ZipFile.**printdir** ()

Print a table of contents for the archive to *sys.stdout*.

ZipFile.**setpassword** (*pwd*)

Set *pwd* as default password to extract encrypted files.

New in version 2.6.

`ZipFile.read(name[, pwd])`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files and, if specified, it will override the default password set with *setpassword()*. Calling *read()* on a closed *ZipFile* will raise a *RuntimeError*.

Changed in version 2.6: *pwd* was added, and *name* can now be a *ZipInfo* object.

`ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return None. Calling *testzip()* on a closed *ZipFile* will raise a *RuntimeError*.

`ZipFile.write(filename[, arcname[, compress_type]])`

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry. The archive must be open with mode 'w' or 'a' – calling *write()* on a *ZipFile* created with mode 'r' will raise a *RuntimeError*. Calling *write()* on a closed *ZipFile* will raise a *RuntimeError*.

Note: There is no official file name encoding for ZIP files. If you have unicode file names, you must convert them to byte strings in your desired encoding before passing them to *write()*. WinZip interprets all file names as encoded in CP437, also known as DOS Latin.

Note: Archive names should be relative to the archive root, that is, they should not start with a path separator.

Note: If *arcname* (or *filename*, if *arcname* is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

`ZipFile.writestr(zinfo_or_arcname, bytes[, compress_type])`

Write the string *bytes* to the archive; *zinfo_or_arcname* is either the file name it will be given in the archive, or a *ZipInfo* instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode 'w' or 'a' – calling *writestr()* on a *ZipFile* created with mode 'r' will raise a *RuntimeError*. Calling *writestr()* on a closed *ZipFile* will raise a *RuntimeError*.

If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo_or_arcname* (if that is a *ZipInfo* instance).

Note: When passing a *ZipInfo* instance as the *zinfo_or_arcname* parameter, the compression method used will be that specified in the *compress_type* member of the given *ZipInfo* instance. By default, the *ZipInfo* constructor sets this member to *ZIP_STORED*.

Changed in version 2.7: The *compress_type* argument.

The following data attributes are also available:

`ZipFile.debug`

The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.comment`

The comment text associated with the ZIP file. If assigning a comment to a *ZipFile* instance created with mode

'a' or 'w', this should be a string no longer than 65535 bytes. Comments longer than this will be truncated in the written archive when `close()` is called.

12.4.2 PyZipFile Objects

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor. Instances have one method in addition to those of `ZipFile` objects.

`PyZipFile.writepy(pathname[, basename])`

Search for files `*.py` and add the corresponding file to the archive. The corresponding file is a `*.pyo` file if available, else a `*.pyc` file, compiling if necessary. If the `pathname` is a file, the filename must end with `.py`, and just the (corresponding `*.py[co]`) file is added at the top level (no path information). If the `pathname` is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.py[co]` are added at the top level. If the directory is a package directory, then all `*.py[co]` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively. `basename` is intended for internal use only. The `writepy()` method makes archives with file names like this:

| | |
|--------------------------------------|--|
| <code>string.pyc</code> | <code># Top level name</code> |
| <code>test/__init__.pyc</code> | <code># Package directory</code> |
| <code>test/test_support.pyc</code> | <code># Module test.test_support</code> |
| <code>test/bogus/__init__.pyc</code> | <code># Subpackage directory</code> |
| <code>test/bogus/myfile.pyc</code> | <code># Submodule test.bogus.myfile</code> |

12.4.3 ZipInfo Objects

Instances of the `ZipInfo` class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Each object stores information about a single member of the ZIP archive.

Instances have the following attributes:

`ZipInfo.filename`

Name of the file in the archive.

`ZipInfo.date_time`

The time and date of the last modification to the archive member. This is a tuple of six values:

| Index | Value |
|-------|--------------------------|
| 0 | Year (≥ 1980) |
| 1 | Month (one-based) |
| 2 | Day of month (one-based) |
| 3 | Hours (zero-based) |
| 4 | Minutes (zero-based) |
| 5 | Seconds (zero-based) |

Note: The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member.

ZipInfo.extra

Expansion field data. The [PKZIP Application Note](#) contains some comments on the internal structure of the data contained in this string.

ZipInfo.create_system

System which created ZIP archive.

ZipInfo.create_version

PKZIP version which created ZIP archive.

ZipInfo.extract_version

PKZIP version needed to extract archive.

ZipInfo.reserved

Must be zero.

ZipInfo.flag_bits

ZIP flag bits.

ZipInfo.volume

Volume number of file header.

ZipInfo.internal_attr

Internal attributes.

ZipInfo.external_attr

External file attributes.

ZipInfo.header_offset

Byte offset to the file header.

ZipInfo.CRC

CRC-32 of the uncompressed file.

ZipInfo.compress_size

Size of the compressed data.

ZipInfo.file_size

Size of the uncompressed file.

12.4.4 Command-Line Interface

The `zipfile` module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

Command-line options

- l** <zipfile>
List files in a zipfile.
- c** <zipfile> <source1> ... <sourceN>
Create zipfile from source files.
- e** <zipfile> <output_dir>
Extract zipfile into target directory.
- t** <zipfile>
Test whether the zipfile is valid or not.

12.5 tarfile — Read and write tar archive files

New in version 2.3.

Source code: [Lib/tarfile.py](#)

The *tarfile* module makes it possible to read and write tar archives, including those using gzip or bz2 compression. Use the *zipfile* module to read or write .zip files, or the higher-level functions in *shutil*.

Some facts and figures:

- reads and writes *gzip* and *bz2* compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for the *sparse* extension.
- read/write support for the POSIX.1-2001 (pax) format.

New in version 2.6.

- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

Note: Handling of multi-stream bzip2 files is not supported. Modules such as *bz2file* let you overcome this.

`tarfile.open` (*name=None, mode='r', fileobj=None, bufsize=10240, **kwargs*)

Return a *TarFile* object for the pathname *name*. For detailed information on *TarFile* objects and the keyword arguments that are allowed, see *TarFile Objects*.

mode has to be a string of the form 'filemode[:compression]', it defaults to 'r'. Here is a full list of mode combinations:

| mode | action |
|--------------|---|
| 'r' or 'r:*' | Open for reading with transparent compression (recommended). |
| 'r:' | Open for reading exclusively without compression. |
| 'r:gz' | Open for reading with gzip compression. |
| 'r:bz2' | Open for reading with bzip2 compression. |
| 'a' or 'a:' | Open for appending with no compression. The file is created if it does not exist. |
| 'w' or 'w:' | Open for uncompressed writing. |
| 'w:gz' | Open for gzip compressed writing. |
| 'w:bz2' | Open for bzip2 compressed writing. |

Note that 'a:gz' or 'a:bz2' is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, `ReadError` is raised. Use *mode* 'r' to avoid this. If a compression method is not supported, `CompressionError` is raised.

If *fileobj* is specified, it is used as an alternative to a file object opened for *name*. It is supposed to be at position 0.

For modes 'w:gz', 'r:gz', 'w:bz2', 'r:bz2', `tarfile.open()` accepts the keyword argument *compresslevel* (default 9) to specify the compression level of the file.

For special purposes, there is a second format for *mode*: 'filemode|[compression]'. `tarfile.open()` will return a `TarFile` object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a `read()` or `write()` method (depending on the *mode*). *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin`, a socket file object or a tape device. However, such a `TarFile` object is limited in that it does not allow random access, see *Examples*. The currently possible modes:

| Mode | Action |
|---------|--|
| 'r *' | Open a <i>stream</i> of tar blocks for reading with transparent compression. |
| 'r ' | Open a <i>stream</i> of uncompressed tar blocks for reading. |
| 'r gz' | Open a gzip compressed <i>stream</i> for reading. |
| 'r bz2' | Open a bzip2 compressed <i>stream</i> for reading. |
| 'w ' | Open an uncompressed <i>stream</i> for writing. |
| 'w gz' | Open a gzip compressed <i>stream</i> for writing. |
| 'w bz2' | Open a bzip2 compressed <i>stream</i> for writing. |

class `tarfile.TarFile`

Class for reading and writing tar archives. Do not use this class directly, better use `tarfile.open()` instead. See *TarFile Objects*.

`tarfile.is_tarfile` (*name*)

Return `True` if *name* is a tar archive file, that the `tarfile` module can read.

class `tarfile.TarFileCompat` (*filename*, *mode*='r', *compression*=`TAR_PLAIN`)

Class for limited access to tar archives with a *zipfile*-like interface. Please consult the documentation of the *zipfile* module for more details. *compression* must be one of the following constants:

TAR_PLAIN

Constant for an uncompressed tar archive.

TAR_GZIPPED

Constant for a *gzip* compressed tar archive.

Deprecated since version 2.6: The `TarFileCompat` class has been removed in Python 3.

exception `tarfile.TarError`

Base class for all `tarfile` exceptions.

exception `tarfile.ReadError`

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

exception `tarfile.CompressionError`

Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception `tarfile.StreamError`

Is raised for the limitations that are typical for stream-like `TarFile` objects.

exception `tarfile.ExtractError`

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel== 2`.

The following constants are available at the module level:

`tarfile.ENCODING`

The default character encoding: 'utf-8' on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

exception `tarfile.HeaderError`

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

New in version 2.6.

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section [Supported tar formats](#) for details.

`tarfile.USTAR_FORMAT`

POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`

GNU tar format.

`tarfile.PAX_FORMAT`

POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`

The default format for creating archives. This is currently `GNU_FORMAT`.

[GNU tar manual, Basic Tar Format](#) Documentation for tar archive files, including GNU tar extensions.

12.5.1 TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see [TarInfo Objects](#) for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the [Examples](#) section for a use case.

New in version 2.7: Added support for the context management protocol.

class `tarfile.TarFile` (*name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT, tarinfo=TarInfo, dereference=False, ignore_zeros=False, encoding=ENCODING, errors=None, pax_headers=None, debug=0, errorlevel=0*)

All following arguments are optional and can be accessed as instance attributes as well.

name is the pathname of the archive. It can be omitted if *fileobj* is given. In this case, the file object's *name* attribute is used if it exists.

mode is either 'r' to read from an existing archive, 'a' to append data to an existing file or 'w' to create a new file overwriting an existing one.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s mode. *fileobj* will be used from position 0.

Note: *fileobj* is not closed, when *TarFile* is closed.

format controls the archive format. It must be one of the constants *USTAR_FORMAT*, *GNU_FORMAT* or *PAX_FORMAT* that are defined at module level.

New in version 2.6.

The *tarinfo* argument can be used to replace the default *TarInfo* class with a different one.

New in version 2.6.

If *dereference* is *False*, add symbolic and hard links to the archive. If it is *True*, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore_zeros* is *False*, treat an empty block as the end of the archive. If it is *True*, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to *sys.stderr*.

If *errorlevel* is 0, all errors are ignored when using *TarFile.extract()*. Nevertheless, they appear as error messages in the debug output, when debugging is enabled. If 1, all *fatal* errors are raised as *OSError* or *IOError* exceptions. If 2, all *non-fatal* errors are raised as *TarError* exceptions as well.

The *encoding* and *errors* arguments control the way strings are converted to unicode objects and vice versa. The default settings will work for most users. See section *Unicode issues* for in-depth information.

New in version 2.6.

The *pax_headers* argument is an optional dictionary of unicode strings which will be added as a pax global header if *format* is *PAX_FORMAT*.

New in version 2.6.

classmethod *TarFile.open(...)*

Alternative constructor. The *tarfile.open()* function is actually a shortcut to this classmethod.

TarFile.getmember(name)

Return a *TarInfo* object for member *name*. If *name* can not be found in the archive, *KeyError* is raised.

Note: If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

TarFile.getmembers()

Return the members of the archive as a list of *TarInfo* objects. The list has the same order as the members in the archive.

TarFile.getnames()

Return the members as a list of their names. It has the same order as the list returned by *getmembers()*.

`TarFile.list(verbose=True)`

Print a table of contents to `sys.stdout`. If `verbose` is `False`, only the names of the members are printed. If it is `True`, output similar to that of `ls -l` is produced.

`TarFile.next()`

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

`TarFile.extractall(path=".", members=None)`

Extract all members from the archive to the current working directory or directory `path`. If optional `members` is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

Warning: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of `path`, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.

New in version 2.5.

`TarFile.extract(member, path="")`

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. `member` may be a filename or a `TarInfo` object. You can specify a different directory using `path`.

Note: The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

Warning: See the warning for `extractall()`.

`TarFile.extractfile(member)`

Extract a member from the archive as a file object. `member` may be a filename or a `TarInfo` object. If `member` is a regular file, a file-like object is returned. If `member` is a link, a file-like object is constructed from the link's target. If `member` is none of the above, `None` is returned.

Note: The file-like object is read-only. It provides the methods `read()`, `readline()`, `readlines()`, `seek()`, `tell()`, and `close()`, and also supports iteration over its lines.

`TarFile.add(name, arcname=None, recursive=True, exclude=None, filter=None)`

Add the file `name` to the archive. `name` may be any type of file (directory, fifo, symbolic link, etc.). If given, `arcname` specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting `recursive` to `False`. If `exclude` is given it must be a function that takes one filename argument and returns a boolean value. Depending on this value the respective file is either excluded (`True`) or added (`False`). If `filter` is specified it must be a function that takes a `TarInfo` object argument and returns the changed `TarInfo` object. If it instead returns `None` the `TarInfo` object will be excluded from the archive. See [Examples](#) for an example.

Changed in version 2.6: Added the `exclude` parameter.

Changed in version 2.7: Added the `filter` parameter.

Deprecated since version 2.7: The *exclude* parameter is deprecated, please use the *filter* parameter instead. For maximum portability, *filter* should be used as a keyword argument rather than as a positional argument so that code won't be affected when *exclude* is ultimately removed.

`TarFile.addfile (tarinfo, fileobj=None)`

Add the *TarInfo* object *tarinfo* to the archive. If *fileobj* is given, *tarinfo.size* bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettinfo()*.

Note: On Windows platforms, *fileobj* should always be opened with mode `'rb'` to avoid irritation about the file size.

`TarFile.gettarinfo (name=None, arcname=None, fileobj=None)`

Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is either named by *name*, or specified as a file object *fileobj* with a file descriptor. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s *name* attribute, or the *name* argument.

You can modify some of the *TarInfo*'s attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

`TarFile.close ()`

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.posix`

Setting this to *True* is equivalent to setting the *format* attribute to *USTAR_FORMAT*, *False* is equivalent to *GNU_FORMAT*.

Changed in version 2.4: *posix* defaults to *False*.

Deprecated since version 2.6: Use the *format* attribute instead.

`TarFile.pax_headers`

A dictionary containing key-value pairs of pax global headers.

New in version 2.6.

12.5.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettinfo()*.

class `tarfile.TarInfo (name='')`

Create a *TarInfo* object.

`TarInfo.frombuf (buf)`

Create and return a *TarInfo* object from string buffer *buf*.

New in version 2.6: Raises *HeaderError* if the buffer is invalid..

`TarInfo.fromtarfile (tarfile)`

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

New in version 2.6.

`TarInfo.tobuf` (*format=DEFAULT_FORMAT, encoding=ENCODING, errors='strict'*)

Create a string buffer from a `TarInfo` object. For information on the arguments see the constructor of the `TarFile` class.

Changed in version 2.6: The arguments were added.

A `TarInfo` object has the following public data attributes:

`TarInfo.name`

Name of the archive member.

`TarInfo.size`

Size in bytes.

`TarInfo.mtime`

Time of last modification.

`TarInfo.mode`

Permission bits.

`TarInfo.type`

File type. *type* is usually one of these constants: `REGTYPE`, `AREGTYPE`, `LNKTYPE`, `SYMTYPE`, `DIRTYPE`, `FIFOTYPE`, `CONTTYPE`, `CHRTYPE`, `BLKTYPE`, `GNUTYPE_SPARSE`. To determine the type of a `TarInfo` object more conveniently, use the `is*()` methods below.

`TarInfo.linkname`

Name of the target file name, which is only present in `TarInfo` objects of type `LNKTYPE` and `SYMTYPE`.

`TarInfo.uid`

User ID of the user who originally stored this member.

`TarInfo.gid`

Group ID of the user who originally stored this member.

`TarInfo.uname`

User name.

`TarInfo.gname`

Group name.

`TarInfo.pax_headers`

A dictionary containing key-value pairs of an associated pax extended header.

New in version 2.6.

A `TarInfo` object also provides some convenient query methods:

`TarInfo.isfile()`

Return `True` if the `TarInfo` object is a regular file.

`TarInfo.isreg()`

Same as `isfile()`.

`TarInfo.isdir()`

Return `True` if it is a directory.

`TarInfo.issym()`

Return `True` if it is a symbolic link.

`TarInfo.islnk()`

Return `True` if it is a hard link.

`TarInfo.ischr()`

Return `True` if it is a character device.

```
TarInfo.isblk()
    Return True if it is a block device.

TarInfo.isfifo()
    Return True if it is a FIFO.

TarInfo.isdev()
    Return True if it is one of character device, block device or FIFO.
```

12.5.3 Examples

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with `TarFile.extractall()` using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print tarinfo.name, "is", tarinfo.size, "bytes in size and is",
    if tarinfo.isreg():
        print "a regular file."
    elif tarinfo.isdir():
        print "a directory."
```

(continues on next page)

(continued from previous page)

```
else:
    print "something else."
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in `TarFile.add()`:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

12.5.4 Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (*USTAR_FORMAT*). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 gigabytes. This is an old and limited but widely supported format.
- The GNU tar format (*GNU_FORMAT*). It supports long filenames and linknames, files bigger than 8 gigabytes and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (*PAX_FORMAT*). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. However, not all tar implementations today are able to handle pax archives properly.

The *pax* format is an extension to the existing *ustar* format. It uses extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

12.5.5 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (that all other formats are merely variants of) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-ASCII characters. Names (i.e. filenames, linknames, user/group names) containing these characters will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive.

The pax format was designed to solve this problem. It stores non-ASCII names using the universal character encoding *UTF-8*. When a pax archive is read, these *UTF-8* names are converted to the encoding of the local file system.

The details of unicode conversion are controlled by the *encoding* and *errors* keyword arguments of the *TarFile* class.

The default value for *encoding* is the local character encoding. It is deduced from *sys.getfilesystemencoding()* and *sys.getdefaultencoding()*. In read mode, *encoding* is used exclusively to convert unicode names from a pax archive to strings in the local character encoding. In write mode, the use of *encoding* depends on the chosen archive format. In case of *PAX_FORMAT*, input names that contain non-ASCII characters need to be decoded before being stored as *UTF-8* strings. The other formats do not make use of *encoding* unless unicode objects are used as input names. These are converted to 8-bit character strings before they are added to the archive.

The *errors* argument defines how characters are treated that cannot be converted to or from *encoding*. Possible values are listed in section *Codec Base Classes*. In read mode, there is an additional scheme `'utf-8'` which means that bad characters are replaced by their *UTF-8* representation. This is the default scheme. In write mode the default value for *errors* is `'strict'` to ensure that name information is not altered unnoticed.

FILE FORMATS

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages or are related to e-mail.

13.1 `csv` — CSV File Reading and Writing

New in version 2.3.

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. There is no “CSV standard”, so the format is operationally defined by the many applications which read and write it. The lack of a standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The `csv` module implements classes to read and write tabular data in CSV format. It allows programmers to say, “write this data in the format preferred by Excel,” or “read data from this file which was generated by Excel,” without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The `csv` module's `reader` and `writer` objects read and write sequences. Programmers can also read and write data in dictionary form using the `DictReader` and `DictWriter` classes.

Note: This version of the `csv` module doesn't support Unicode input. Also, there are currently some issues regarding ASCII NUL characters. Accordingly, all input should be UTF-8 or printable ASCII to be safe; see the examples in section [Examples](#).

See also:

PEP 305 - CSV File API The Python Enhancement Proposal which proposed this addition to Python.

13.1.1 Module Contents

The `csv` module defines the following functions:

`csv.reader(csvfile, dialect='excel', **fmtparams)`

Return a reader object which will iterate over lines in the given `csvfile`. `csvfile` can be any object which supports the `iterator` protocol and returns a string each time its `next()` method is called — file objects and list objects are both suitable. If `csvfile` is a file object, it must be opened with the 'b' flag on platforms where that makes a difference. An optional `dialect` parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the `Dialect` class or one of the strings returned by

the `list_dialects()` function. The other optional `fmtparams` keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section [Dialects and Formatting Parameters](#).

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed.

A short usage example:

```
>>> import csv
>>> with open('eggs.csv', 'rb') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print ', '.join(row)
Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

Changed in version 2.5: The parser is now stricter with respect to multi-line quoted fields. Previously, if a line ended within a quoted field without a terminating newline character, a newline would be inserted into the returned field. This behavior caused problems when reading files which contained carriage return characters within fields. The behavior was changed to return the field without inserting newlines. As a consequence, if newlines embedded within fields are important, the input should be split into lines in a manner which preserves the newline characters.

`csv.writer(csvfile, dialect='excel', **fmtparams)`

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. `csvfile` can be any object with a `write()` method. If `csvfile` is a file object, it must be opened with the 'b' flag on platforms where that makes a difference. An optional `dialect` parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the [Dialect](#) class or one of the strings returned by the `list_dialects()` function. The other optional `fmtparams` keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section [Dialects and Formatting Parameters](#). To make it as easy as possible to interface with modules which implement the DB API, the value `None` is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. Floats are stringified with `repr()` before being written. All other non-string data are stringified with `str()` before being written.

A short usage example:

```
import csv
with open('eggs.csv', 'wb') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                           quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

`csv.register_dialect(name[, dialect], **fmtparams)`

Associate `dialect` with `name`. `name` must be a string or Unicode object. The dialect can be specified either by passing a sub-class of [Dialect](#), or by `fmtparams` keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about the dialect and formatting parameters, see section [Dialects and Formatting Parameters](#).

`csv.unregister_dialect(name)`

Delete the dialect associated with `name` from the dialect registry. An [Error](#) is raised if `name` is not a registered dialect name.

`csv.get_dialect(name)`

Return the dialect associated with `name`. An [Error](#) is raised if `name` is not a registered dialect name.

Changed in version 2.5: This function now returns an immutable [Dialect](#). Previously an instance of the requested dialect was returned. Users could modify the underlying class, changing the behavior of active readers and writers.

`csv.list_dialects()`

Return the names of all registered dialects.

`csv.field_size_limit([new_limit])`

Returns the current maximum field size allowed by the parser. If *new_limit* is given, this becomes the new limit.

New in version 2.5.

The `csv` module defines the following classes:

class `csv.DictReader`(*f*, *fieldnames*=None, *restkey*=None, *restval*=None, *dialect*='excel', *args, **kwds)

Create an object which operates like a regular reader but maps the information read into a dict whose keys are given by the optional *fieldnames* parameter. The *fieldnames* parameter is a [sequence](#) whose elements are associated with the fields of the input data in order. These elements become the keys of the resulting dictionary. If the *fieldnames* parameter is omitted, the values in the first row of the file *f* will be used as the fieldnames. If the row read has more fields than the fieldnames sequence, the remaining data is added as a sequence keyed by the value of *restkey*. If the row read has fewer fields than the fieldnames sequence, the remaining keys take the value of the optional *restval* parameter. Any other optional or keyword arguments are passed to the underlying [reader](#) instance.

A short usage example:

```
>>> import csv
>>> with open('names.csv') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Baked Beans
Lovely Spam
Wonderful Spam
```

class `csv.DictWriter`(*f*, *fieldnames*, *restval*=", *extrasaction*='raise', *dialect*='excel', *args, **kwds)

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a [sequence](#) of keys that identify the order in which values in the dictionary passed to the `writerow()` method are written to the file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the `writerow()` method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to 'raise' a [ValueError](#) is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying [writer](#) instance.

Note that unlike the [DictReader](#) class, the *fieldnames* parameter of the [DictWriter](#) is not optional. Since Python's *dict* objects are not ordered, there is not enough information available to deduce the order in which the row should be written to the file *f*.

A short usage example:

```
import csv

with open('names.csv', 'w') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

class `csv.Dialect`

The [Dialect](#) class is a container class relied on primarily for its attributes, which are used to define the parameters

for a specific *reader* or *writer* instance.

class `csv.excel`

The *excel* class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class `csv.excel_tab`

The *excel_tab* class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class `csv.Sniffer`

The *Sniffer* class is used to deduce the format of a CSV file.

The *Sniffer* class provides two methods:

sniff (*sample*, *delimiters=None*)

Analyze the given *sample* and return a *Dialect* subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

has_header (*sample*)

Analyze the sample text (presumed to be in CSV format) and return *True* if the first row appears to be a series of column headers.

An example for *Sniffer* use:

```
with open('example.csv', 'rb') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

The *csv* module defines the following constants:

`csv.QUOTE_ALL`

Instructs *writer* objects to quote all fields.

`csv.QUOTE_MINIMAL`

Instructs *writer* objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

`csv.QUOTE_NONNUMERIC`

Instructs *writer* objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type *float*.

`csv.QUOTE_NONE`

Instructs *writer* objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by the current *escapechar* character. If *escapechar* is not set, the writer will raise *Error* if any characters that require escaping are encountered.

Instructs *reader* to perform no special processing of quote characters.

The *csv* module defines the following exception:

exception `csv.Error`

Raised by any of the functions when an error is detected.

13.1.2 Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the *Dialect* class having a set of specific methods and a single `validate()`

method. When creating *reader* or *writer* objects, the programmer can specify a string or a subclass of the *Dialect* class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the *Dialect* class.

Dialects support the following attributes:

Dialect.delimiter

A one-character string used to separate fields. It defaults to `' , '`.

Dialect.doublequote

Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When *True*, the character is doubled. When *False*, the *escapechar* is used as a prefix to the *quotechar*. It defaults to *True*.

On output, if *doublequote* is *False* and no *escapechar* is set, *Error* is raised if a *quotechar* is found in a field.

Dialect.escapechar

A one-character string used by the writer to escape the *delimiter* if *quoting* is set to *QUOTE_NONE* and the *quotechar* if *doublequote* is *False*. On reading, the *escapechar* removes any special meaning from the following character. It defaults to *None*, which disables escaping.

Dialect.lineterminator

The string used to terminate lines produced by the *writer*. It defaults to `'\r\n'`.

Note: The *reader* is hard-coded to recognise either `'\r'` or `'\n'` as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

Dialect.quotechar

A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to `'\"'`.

Dialect.quoting

Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the *QUOTE_** constants (see section *Module Contents*) and defaults to *QUOTE_MINIMAL*.

Dialect.skipinitialspace

When *True*, whitespace immediately following the *delimiter* is ignored. The default is *False*.

Dialect.strict

When *True*, raise exception *Error* on bad CSV input. The default is *False*.

13.1.3 Reader Objects

Reader objects (*DictReader* instances and objects returned by the *reader()* function) have the following public methods:

csvreader.next()

Return the next row of the reader's iterable object as a list, parsed according to the current dialect.

Reader objects have the following public attributes:

csvreader.dialect

A read-only description of the dialect in use by the parser.

csvreader.line_num

The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

New in version 2.5.

DictReader objects have the following public attribute:

`csvreader.fieldnames`

If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

Changed in version 2.6.

13.1.4 Writer Objects

Writer objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be a sequence of strings or numbers for Writer objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

`csvwriter.writerow(row)`

Write the *row* parameter to the writer's file object, formatted according to the current dialect.

`csvwriter.writerows(rows)`

Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

`csvwriter.dialect`

A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

`DictWriter.writeheader()`

Write a row with the field names (as specified in the constructor).

New in version 2.7.

13.1.5 Examples

The simplest example of reading a CSV file:

```
import csv
with open('some.csv', 'rb') as f:
    reader = csv.reader(f)
    for row in reader:
        print row
```

Reading a file with an alternate format:

```
import csv
with open('passwd', 'rb') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print row
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'wb') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', 'rb') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, 'rb') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print row
    except csv.Error as e:
        sys.exit('file %s, line %d: %s' % (filename, reader.line_num, e))
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print row
```

The `csv` module doesn't directly support reading and writing Unicode, but it is 8-bit-clean save for some problems with ASCII NUL characters. So you can write functions or classes that handle the encoding and decoding for you as long as you avoid encodings like UTF-16 that use NULs. UTF-8 is recommended.

`unicode_csv_reader()` below is a *generator* that wraps `csv.reader` to handle Unicode CSV data (a list of Unicode strings). `utf_8_encoder()` is a *generator* that encodes the Unicode strings as UTF-8, one string (or row) at a time. The encoded strings are parsed by the CSV reader, and `unicode_csv_reader()` decodes the UTF-8-encoded cells back into Unicode:

```
import csv

def unicode_csv_reader(unicode_csv_data, dialect=csv.excel, **kwargs):
    # csv.py doesn't do Unicode; encode temporarily as UTF-8:
    csv_reader = csv.reader(utf_8_encoder(unicode_csv_data),
                            dialect=dialect, **kwargs)
    for row in csv_reader:
        # decode UTF-8 back to Unicode, cell by cell:
        yield [unicode(cell, 'utf-8') for cell in row]

def utf_8_encoder(unicode_csv_data):
    for line in unicode_csv_data:
        yield line.encode('utf-8')
```

For all other encodings the following `UnicodeReader` and `UnicodeWriter` classes can be used. They take an additional *encoding* parameter in their constructor and make sure that the data passes the real reader or writer encoded as UTF-8:

```
import csv, codecs, cStringIO

class UTF8Recoder:
    """
    Iterator that reads an encoded stream and reencodes the input to UTF-8
    """
    def __init__(self, f, encoding):
        self.reader = codecs.getreader(encoding)(f)

    def __iter__(self):
        return self

    def next(self):
        return self.reader.next().encode("utf-8")

class UnicodeReader:
    """
    A CSV reader which will iterate over lines in the CSV file "f",
    which is encoded in the given encoding.
    """

    def __init__(self, f, dialect=csv.excel, encoding="utf-8", **kwds):
        f = UTF8Recoder(f, encoding)
        self.reader = csv.reader(f, dialect=dialect, **kwds)

    def next(self):
        row = self.reader.next()
        return [unicode(s, "utf-8") for s in row]

    def __iter__(self):
        return self

class UnicodeWriter:
    """
    A CSV writer which will write rows to CSV file "f",
    which is encoded in the given encoding.
    """

    def __init__(self, f, dialect=csv.excel, encoding="utf-8", **kwds):
        # Redirect output to a queue
        self.queue = cStringIO.StringIO()
        self.writer = csv.writer(self.queue, dialect=dialect, **kwds)
        self.stream = f
        self.encoder = codecs.getincrementalencoder(encoding)()

    def writerow(self, row):
        self.writer.writerow([s.encode("utf-8") for s in row])
        # Fetch UTF-8 output from the queue ...
        data = self.queue.getvalue()
        data = data.decode("utf-8")
        # ... and reencode it into the target encoding
        data = self.encoder.encode(data)
        # write to the target stream
        self.stream.write(data)
        # empty queue
        self.queue.truncate(0)
```

(continues on next page)

(continued from previous page)

```
def writerows(self, rows):
    for row in rows:
        self.writerow(row)
```

13.2 ConfigParser — Configuration file parser

Note: The `ConfigParser` module has been renamed to `configparser` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

This module defines the class `ConfigParser`. The `ConfigParser` class implements a basic configuration file parser language which provides a structure similar to what you would find on Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

Note: This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

See also:

Module `shlex` Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

Module `json` The `json` module implements a subset of JavaScript syntax which can also be used for this purpose.

The configuration file consists of sections, led by a `[section]` header and followed by `name: value` entries, with continuations in the style of **RFC 822** (see section 3.1.1, “LONG HEADER FIELDS”); `name=value` is also accepted. Note that leading whitespace is removed from values. The optional values can contain format strings which refer to other values in the same section, or values in a special `DEFAULT` section. Additional defaults can be provided on initialization and retrieval. Lines beginning with `'#'` or `';'` are ignored and may be used to provide comments.

Configuration files may include comments, prefixed by specific characters (`#` and `;`). Comments may appear on their own in an otherwise empty line, or may be entered in lines holding values or section names. In the latter case, they need to be preceded by a whitespace character to be recognized as a comment. (For backwards compatibility, only `;` starts an inline comment, while `#` does not.)

On top of the core functionality, `SafeConfigParser` supports interpolation. This means values can contain format strings which refer to other values in the same section, or values in a special `DEFAULT` section. Additional defaults can be provided on initialization.

For example:

```
[My Section]
foodir: %(dir)s/whatever
dir=frob
long: this value continues
    in the next line
```

would resolve the `%(dir)s` to the value of `dir` (`frob` in this case). All reference expansions are done on demand.

Default values can be specified by passing them into the `ConfigParser` constructor as a dictionary. Additional defaults may be passed into the `get()` method which will override all others.

Sections are normally stored in a built-in dictionary. An alternative dictionary type can be passed to the `ConfigParser` constructor. For example, if a dictionary type is passed that sorts its keys, the sections will be sorted on write-back, as will be the keys within each section.

class `ConfigParser.RawConfigParser` (`[defaults[, dict_type[, allow_no_value]]]`)

The basic configuration object. When `defaults` is given, it is initialized into the dictionary of intrinsic defaults. When `dict_type` is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values. When `allow_no_value` is true (default: `False`), options without values are accepted; the value presented for these is `None`.

This class does not support the magical interpolation behavior.

All option names are passed through the `optionxform()` method. Its default implementation converts option names to lower case.

New in version 2.3.

Changed in version 2.6: `dict_type` was added.

Changed in version 2.7: The default `dict_type` is `collections.OrderedDict`. `allow_no_value` was added.

class `ConfigParser.ConfigParser` (`[defaults[, dict_type[, allow_no_value]]]`)

Derived class of `RawConfigParser` that implements the magical interpolation feature and adds optional arguments to the `get()` and `items()` methods. The values in `defaults` must be appropriate for the `%()`s string interpolation. Note that `__name__` is an intrinsic default; its value is the section name, and will override any value provided in `defaults`.

All option names used in interpolation will be passed through the `optionxform()` method just like any other option name reference. Using the default implementation of `optionxform()`, the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

New in version 2.3.

Changed in version 2.6: `dict_type` was added.

Changed in version 2.7: The default `dict_type` is `collections.OrderedDict`. `allow_no_value` was added.

class `ConfigParser.SafeConfigParser` (`[defaults[, dict_type[, allow_no_value]]]`)

Derived class of `ConfigParser` that implements a more-sane variant of the magical interpolation feature. This implementation is more predictable as well. New applications should prefer this version if they don't need to be compatible with older versions of Python.

New in version 2.3.

Changed in version 2.6: `dict_type` was added.

Changed in version 2.7: The default `dict_type` is `collections.OrderedDict`. `allow_no_value` was added.

exception `ConfigParser.Error`

Base class for all other configparser exceptions.

exception `ConfigParser.NoSectionError`

Exception raised when a specified section is not found.

exception `ConfigParser.DuplicateSectionError`

Exception raised if `add_section()` is called with the name of a section that is already present.

exception `ConfigParser.NoOptionError`

Exception raised when a specified option is not found in the specified section.

exception `ConfigParser.InterpolationError`

Base class for exceptions raised when problems occur performing string interpolation.

exception `ConfigParser.InterpolationDepthError`

Exception raised when string interpolation cannot be completed because the number of iterations exceeds `MAX_INTERPOLATION_DEPTH`. Subclass of `InterpolationError`.

exception `ConfigParser.InterpolationMissingOptionError`

Exception raised when an option referenced from a value does not exist. Subclass of `InterpolationError`.

New in version 2.3.

exception `ConfigParser.InterpolationSyntaxError`

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of `InterpolationError`.

New in version 2.3.

exception `ConfigParser.MissingSectionHeaderError`

Exception raised when attempting to parse a file which has no section headers.

exception `ConfigParser.ParsingError`

Exception raised when errors occur attempting to parse a file.

`ConfigParser.MAX_INTERPOLATION_DEPTH`

The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only for the `ConfigParser` class.

See also:

Module `shlex` Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

13.2.1 RawConfigParser Objects

`RawConfigParser` instances have the following methods:

`RawConfigParser.defaults()`

Return a dictionary containing the instance-wide defaults.

`RawConfigParser.sections()`

Return a list of the sections available; `DEFAULT` is not included in the list.

`RawConfigParser.add_section(section)`

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the name `DEFAULT` (or any of its case-insensitive variants) is passed, `ValueError` is raised.

`RawConfigParser.has_section(section)`

Indicates whether the named section is present in the configuration. The `DEFAULT` section is not acknowledged.

`RawConfigParser.options(section)`

Returns a list of options available in the specified *section*.

`RawConfigParser.has_option(section, option)`

If the given section exists, and contains the given option, return `True`; otherwise return `False`.

New in version 1.6.

`RawConfigParser.read(filenames)`

Attempt to read and parse a list of filenames, returning a list of filenames which were successfully parsed. If *filenames* is a string or Unicode string, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify a list of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all

existing configuration files in the list will be read. If none of the named files exist, the *ConfigParser* instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using *readfp()* before calling *read()* for any optional files:

```
import ConfigParser, os

config = ConfigParser.ConfigParser()
config.readfp(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')])
```

Changed in version 2.4: Returns list of successfully parsed filenames.

RawConfigParser.readfp(*fp*[, *filename*])

Read and parse configuration data from the file or file-like object in *fp* (only the *readline()* method is used). If *filename* is omitted and *fp* has a *name* attribute, that is used for *filename*; the default is <???>.

RawConfigParser.get(*section*, *option*)

Get an *option* value for the named *section*.

RawConfigParser.getint(*section*, *option*)

A convenience method which coerces the *option* in the specified *section* to an integer.

RawConfigParser.getfloat(*section*, *option*)

A convenience method which coerces the *option* in the specified *section* to a floating point number.

RawConfigParser.getboolean(*section*, *option*)

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are "1", "yes", "true", and "on", which cause this method to return *True*, and "0", "no", "false", and "off", which cause it to return *False*. These string values are checked in a case-insensitive manner. Any other value will cause it to raise *ValueError*.

RawConfigParser.items(*section*)

Return a list of (name, value) pairs for each option in the given *section*.

RawConfigParser.set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. While it is possible to use *RawConfigParser* (or *ConfigParser* with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

New in version 1.6.

RawConfigParser.write(*fileobject*)

Write a representation of the configuration to the specified file object. This representation can be parsed by a future *read()* call.

New in version 1.6.

RawConfigParser.remove_option(*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise *NoSectionError*. If the option existed to be removed, return *True*; otherwise return *False*.

New in version 1.6.

RawConfigParser.remove_section(*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return *True*. Otherwise return *False*.

RawConfigParser.optionxform(*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't necessarily need to subclass a `ConfigParser` to use this method, you can also re-set it on an instance, to a function that takes a string argument. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
...
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names are stripped before `optionxform()` is called.

13.2.2 ConfigParser Objects

The `ConfigParser` class extends some methods of the `RawConfigParser` interface, adding some optional arguments.

`ConfigParser.get(section, option[, raw[, vars]])`

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *defaults* in that order.

All the '%' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

`ConfigParser.items(section[, raw[, vars]])`

Return a list of (name, value) pairs for each option in the given *section*. Optional arguments have the same meaning as for the `get()` method.

New in version 2.3.

13.2.3 SafeConfigParser Objects

The `SafeConfigParser` class implements the same extended interface as `ConfigParser`, with the following addition:

`SafeConfigParser.set(section, option, value)`

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. *value* must be a string (*str* or *unicode*); if not, `TypeError` is raised.

New in version 2.4.

13.2.4 Examples

An example of writing to a configuration file:

```
import ConfigParser

config = ConfigParser.RawConfigParser()

# When adding sections or items, add them in the reverse order of
# how you want them to be displayed in the actual file.
# In addition, please note that using RawConfigParser's and the raw
# mode of ConfigParser's respective set functions, you can assign
# non-string values to keys internally, but will receive an error
# when attempting to write to a file or when you get it in non-raw
# mode. SafeConfigParser does not allow such assignments to take place.
config.add_section('Section1')
```

(continues on next page)

(continued from previous page)

```

config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'wb') as configfile:
    config.write(configfile)

```

An example of reading the configuration file again:

```

import ConfigParser

config = ConfigParser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print a_float + an_int

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print config.get('Section1', 'foo')

```

To get interpolation, you will need to use a *ConfigParser* or *SafeConfigParser*:

```

import ConfigParser

config = ConfigParser.ConfigParser()
config.read('example.cfg')

# Set the third, optional argument of get to 1 if you wish to use raw mode.
print config.get('Section1', 'foo', 0) # -> "Python is fun!"
print config.get('Section1', 'foo', 1) # -> "%(bar)s is %(baz)s!"

# The optional fourth argument is a dict with members that will take
# precedence in interpolation.
print config.get('Section1', 'foo', 0, {'bar': 'Documentation',
                                         'baz': 'evil'})

```

Defaults are available in all three types of *ConfigParsers*. They are used in interpolation if an option used is not defined elsewhere.

```

import ConfigParser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = ConfigParser.SafeConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print config.get('Section1', 'foo') # -> "Python is fun!"
config.remove_option('Section1', 'bar')

```

(continues on next page)

(continued from previous page)

```
config.remove_option('Section1', 'baz')
print config.get('Section1', 'foo')  # -> "Life is hard!"
```

The function `opt_move` below can be used to move options between sections:

```
def opt_move(config, section1, section2, option):
    try:
        config.set(section2, option, config.get(section1, option, 1))
    except ConfigParser.NoSectionError:
        # Create non-existent section
        config.add_section(section2)
        opt_move(config, section1, section2, option)
    else:
        config.remove_option(section1, option)
```

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `ConfigParser`. The `allow_no_value` parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import ConfigParser
>>> import io

>>> sample_config = """
... [mysqld]
... user = mysql
... pid-file = /var/run/mysqld/mysqld.pid
... skip-external-locking
... old_passwords = 1
... skip-bdb
... skip-innodb
... """

13.3 robotparser — Parser for robots.txt

Note: The `robotparser` module has been renamed `urllib.robotparser` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

This module provides a single class, `RobotFileParser`, which answers questions about whether or not a particular

user agent can fetch a URL on the Web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see <http://www.robotstxt.org/orig.html>.

class `robotparser.RobotFileParser` (*url*=")

This class provides methods to read, parse and answer questions about the `robots.txt` file at *url*.

set_url (*url*)

Sets the URL referring to a `robots.txt` file.

read ()

Reads the `robots.txt` URL and feeds it to the parser.

parse (*lines*)

Parses the *lines* argument.

can_fetch (*useragent*, *url*)

Returns True if the *useragent* is allowed to fetch the *url* according to the rules contained in the parsed `robots.txt` file.

mtime ()

Returns the time the `robots.txt` file was last fetched. This is useful for long-running web spiders that need to check for new `robots.txt` files periodically.

modified ()

Sets the time the `robots.txt` file was last fetched to the current time.

The following example demonstrates basic use of the `RobotFileParser` class.

```
>>> import robotparser
>>> rp = robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```

13.4 netrc — netrc file processing

New in version 1.5.2.

Source code: [Lib/netrc.py](#)

The `netrc` class parses and encapsulates the `netrc` file format used by the Unix **ftp** program and other FTP clients.

class `netrc.netrc` ([*file*])

A `netrc` instance or subclass instance encapsulates data from a `netrc` file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory will be read. Parse errors will raise `NetrcParseError` with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file will raise a `NetrcParseError` if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of `ftp` and other programs that use `.netrc`.

Changed in version 2.7.6: Added the POSIX permissions check.

exception `netrc.NetrcParseError`

Exception raised by the `netrc` class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: `msg` is a textual explanation of the error, `filename` is the name of the source file, and `lineno` gives the line number on which the error was found.

13.4.1 netrc Objects

A `netrc` instance has the following methods:

`netrc.authenticators` (*host*)

Return a 3-tuple (`login`, `account`, `password`) of authenticators for *host*. If the `netrc` file did not contain an entry for the given host, return the tuple associated with the 'default' entry. If neither matching host nor default entry is available, return `None`.

`netrc.__repr__` ()

Dump the class data as a string in the format of a `netrc` file. (This discards comments and may reorder the entries.)

Instances of `netrc` have public instance variables:

`netrc.hosts`

Dictionary mapping host names to (`login`, `account`, `password`) tuples. The 'default' entry, if any, is represented as a pseudo-host by that name.

`netrc.macros`

Dictionary mapping macro names to string lists.

Note: Passwords are limited to a subset of the ASCII character set. Versions of this module prior to 2.3 were extremely limited. Starting with 2.3, all ASCII punctuation is allowed in passwords. However, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the `.netrc` file is parsed and may be removed in the future.

13.5 xdrlib — Encode and decode XDR data

Source code: `Lib/xdrlib.py`

The `xdrlib` module supports the External Data Representation Standard as described in [RFC 1014](#), written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The `xdrlib` module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

class `xdrlib.Packer`

`Packer` is the class for packing data into XDR representation. The `Packer` class is instantiated with no arguments.

class `xdrlib.Unpacker` (*data*)

`Unpacker` is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

See also:

RFC 1014 - XDR: External Data Representation Standard This RFC defined the encoding of data which was XDR at the time this module was originally written. It has apparently been obsoleted by [RFC 1832](#).

RFC 1832 - XDR: External Data Representation Standard Newer RFC that provides a revised definition of XDR.

13.5.1 Packer Objects

Packer instances have the following methods:

`Packer.get_buffer()`
Returns the current pack buffer as a string.

`Packer.reset()`
Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: `pack_uint()`, `pack_int()`, `pack_enum()`, `pack_bool()`, `pack_uhyper()`, and `pack_hyper()`.

`Packer.pack_float(value)`
Packs the single-precision floating point number *value*.

`Packer.pack_double(value)`
Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data:

`Packer.pack_fstring(n, s)`
Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with null bytes if necessary to guaranteed 4 byte alignment.

`Packer.pack_fopaque(n, data)`
Packs a fixed length opaque data stream, similarly to `pack_fstring()`.

`Packer.pack_string(s)`
Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with `pack_fstring()`.

`Packer.pack_opaque(data)`
Packs a variable length opaque data string, similarly to `pack_string()`.

`Packer.pack_bytes(bytes)`
Packs a variable length byte stream, similarly to `pack_string()`.

The following methods support packing arrays and lists:

`Packer.pack_list(list, pack_item)`
Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer 1 is packed first, followed by the data value from the list. *pack_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer 0 is packed.

For example, to pack a list of integers, the code might appear like this:

```
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

`Packer.pack_farray(n, array, pack_item)`
Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is *not* packed into the buffer, but a *ValueError* exception is raised if `len(array)` is not equal to *n*. As above, *pack_item* is the function used to pack each element.

`Packer.pack_array(list, pack_item)`

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in `pack_farray()` above.

13.5.2 Unpacker Objects

The `Unpacker` class offers the following methods:

`Unpacker.reset(data)`

Resets the string buffer with the given *data*.

`Unpacker.get_position()`

Returns the current unpack position in the data buffer.

`Unpacker.set_position(position)`

Sets the data buffer unpack position to *position*. You should be careful about using `get_position()` and `set_position()`.

`Unpacker.get_buffer()`

Returns the current unpack data buffer as a string.

`Unpacker.done()`

Indicates unpack completion. Raises an `Error` exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a `Packer`, can be unpacked with an `Unpacker`. Unpacking methods are of the form `unpack_type()`, and take no arguments. They return the unpacked object.

`Unpacker.unpack_float()`

Unpacks a single-precision floating point number.

`Unpacker.unpack_double()`

Unpacks a double-precision floating point number, similarly to `unpack_float()`.

In addition, the following methods unpack strings, bytes, and opaque data:

`Unpacker.unpack_fstring(n)`

Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

`Unpacker.unpack_fopaque(n)`

Unpacks and returns a fixed length opaque data stream, similarly to `unpack_fstring()`.

`Unpacker.unpack_string()`

Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with `unpack_fstring()`.

`Unpacker.unpack_opaque()`

Unpacks and returns a variable length opaque data string, similarly to `unpack_string()`.

`Unpacker.unpack_bytes()`

Unpacks and returns a variable length byte stream, similarly to `unpack_string()`.

The following methods support unpacking arrays and lists:

`Unpacker.unpack_list(unpack_item)`

Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is 1, then the item is unpacked and appended to the list. A flag of 0 indicates the end of the list. *unpack_item* is the function that is called to unpack the items.

`Unpacker.unpack_farray(n, unpack_item)`

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack_item* is the function used to unpack each element.

`Unpacker.unpack_array(unpack_item)`

Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in `unpack_farray()` above.

13.5.3 Exceptions

Exceptions in this module are coded as class instances:

exception `xdrlib.Error`

The base exception class. *Error* has a single public attribute `msg` containing the description of the error.

exception `xdrlib.ConversionError`

Class derived from *Error*. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions:

```
import xdrlib
p = xdrlib.Packer()
try:
    p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print 'packing the double failed:', instance.msg
```

13.6 plistlib — Generate and parse Mac OS X .plist files

Changed in version 2.6: This module was previously only available in the Mac-specific library, it is now available for all platforms.

Source code: [Lib/plistlib.py](#)

This module provides an interface for reading and writing the “property list” XML files used mainly by Mac OS X.

The property list (*.plist*) file format is a simple XML pickle supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), *Data* or *datetime.datetime* objects. String values (including dictionary keys) may be unicode strings – they will be written out as UTF-8.

The `<data>` plist type is supported through the *Data* class. This is a thin wrapper around a Python string. Use *Data* if your strings contain control characters.

See also:

PList manual page Apple’s documentation of the file format.

This module defines the following functions:

`plistlib.readPlist(pathOrFile)`

Read a plist file. *pathOrFile* may either be a file name or a (readable) file object. Return the unpacked root object (which usually is a dictionary).

The XML data is parsed using the Expat parser from `xml.parsers.expat` – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

`plistlib.writePlist (rootObject, pathOrFile)`

Write *rootObject* to a plist file. *pathOrFile* may either be a file name or a (writable) file object.

A `TypeError` will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

`plistlib.readPlistFromString (data)`

Read a plist from a string. Return the root object.

`plistlib.writePlistToString (rootObject)`

Return *rootObject* as a plist-formatted string.

`plistlib.readPlistFromResource (path, restype='plst', resid=0)`

Read a plist from the resource with type *restype* from the resource fork of *path*. Availability: Mac OS X.

Note: In Python 3.x, this function has been removed.

`plistlib.writePlistToResource (rootObject, path, restype='plst', resid=0)`

Write *rootObject* as a resource with type *restype* to the resource fork of *path*. Availability: Mac OS X.

Note: In Python 3.x, this function has been removed.

The following class is available:

class `plistlib.Data (data)`

Return a “data” wrapper object around the string *data*. This is used in functions converting from/to plists to represent the <data> type available in plists.

It has one attribute, *data*, that can be used to retrieve the Python string stored in it.

13.6.1 Examples

Generating a plist:

```
pl = dict(
    aString="Doodah",
    aList=["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict=dict(
        anotherString="<hello & hi there!>",
        aUnicodeValue=u'M\ue4ssig, Ma\xdf',
        aTrueValue=True,
        aFalseValue=False,
    ),
    someData = Data("<binary gunk>"),
    someMoreData = Data("<lots of binary gunk>" * 10),
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime()))),
)
# unicode keys are possible, but a little awkward to use:
pl[u'\xc5benraa'] = "That was a unicode key."
writePlist(pl, fileName)
```

Parsing a plist:

```
p1 = readPlist(pathOrFile)
print p1["aKey"]
```

CRYPTOGRAPHIC SERVICES

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. Here's an overview:

14.1 `hashlib` — Secure hashes and message digests

New in version 2.5.

Source code: [Lib/hashlib.py](#)

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet [RFC 1321](#)). The terms secure hash and message digest are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

Note: If you want the `adler32` or `crc32` hash functions, they are available in the [`zlib`](#) module.

Warning: Some algorithms have known hash collision weaknesses, refer to the “See also” section at the end.

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha1()` to create a SHA1 hash object. You can now feed this object with arbitrary strings using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the strings fed to it so far using the `digest()` or `hexdigest()` methods.

Constructors for hash algorithms that are always present in this module are [`md5\(\)`](#), `sha1()`, `sha224()`, `sha256()`, `sha384()`, and `sha512()`. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform.

For example, to obtain the digest of the string 'Nobody inspects the spammish repetition':

```
>>> import hashlib
>>> m = hashlib.md5()
>>> m.update("Nobody inspects")
>>> m.update(" the spammish repetition")
>>> m.digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
>>> m.digest_size
16
```

(continues on next page)

(continued from previous page)

```
>>> m.block_size
64
```

More condensed:

```
>>> hashlib.sha224("Nobody inspects the spammish repetition").hexdigest()
'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'
```

A generic `new()` constructor that takes the string name of the desired algorithm as its first parameter also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer. The named constructors are much faster than `new()` and should be preferred.

Using `new()` with an algorithm provided by OpenSSL:

```
>>> h = hashlib.new('ripemd160')
>>> h.update("Nobody inspects the spammish repetition")
>>> h.hexdigest()
'cc4a5ce1b3df48aec5d22d1f16b894a0b894eccc'
```

This module provides the following constant attribute:

hashlib.algorithms

A tuple providing the names of the hash algorithms guaranteed to be supported by this module.

New in version 2.7.

hashlib.algorithms_guaranteed

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms.

New in version 2.7.9.

hashlib.algorithms_available

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to `new()`. `algorithms_guaranteed` will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

New in version 2.7.9.

The following values are provided as constant attributes of the hash objects returned by the constructors:

hash.digest_size

The size of the resulting hash in bytes.

hash.block_size

The internal block size of the hash algorithm in bytes.

A hash object has the following methods:

hash.update(*arg*)

Update the hash object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a)`; `m.update(b)` is equivalent to `m.update(a+b)`.

Changed in version 2.7: The Python GIL is released to allow other threads to run while hash updates on data larger than 2048 bytes is taking place when using hash algorithms supplied by OpenSSL.

hash.digest()

Return the digest of the strings passed to the `update()` method so far. This is a string of `digest_size` bytes which may contain non-ASCII characters, including null bytes.

`hash.hexdigest()`

Like `digest()` except the digest is returned as a string of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`

Return a copy (“clone”) of the hash object. This can be used to efficiently compute the digests of strings that share a common initial substring.

14.1.1 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a `salt`.

`hashlib.pbkdf2_hmac(name, password, salt, rounds, dklen=None)`

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *name* is the desired name of the hash digest algorithm for HMAC, e.g. ‘sha1’ or ‘sha256’. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible value (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of *rounds* should be chosen based on the hash algorithm and computing power. As of 2013, at least 100,000 rounds of SHA-256 is suggested.

dklen is the length of the derived key. If *dklen* is `None` then the digest size of the hash algorithm *name* is used, e.g. 64 for SHA-512.

```
>>> import hashlib, binascii
>>> dk = hashlib.pbkdf2_hmac('sha256', b'password', b'salt', 100000)
>>> binascii.hexlify(dk)
b'0394a2ede332c9a13eb82e9b24631604c31df978b4e2f0fbd2c549944f9d79a5'
```

New in version 2.7.8.

Note: A fast implementation of `pbkdf2_hmac` is available with OpenSSL. The Python implementation uses an inline version of `hmac`. It is about three times slower and doesn’t release the GIL.

See also:

Module `hmac` A module to generate message authentication codes using hashes.

Module `base64` Another way to encode binary hashes for non-binary environments.

<http://csrc.nist.gov/publications/fips/fips180-2/fips180-2.pdf> The FIPS 180-2 publication on Secure Hash Algorithms.

https://en.wikipedia.org/wiki/Cryptographic_hash_function#Cryptographic_hash_algorithms Wikipedia article with information on which algorithms have known issues and what that means regarding their use.

14.2 hmac — Keyed-Hashing for Message Authentication

New in version 2.2.

Source code: [Lib/hmac.py](#)

This module implements the HMAC algorithm as described by [RFC 2104](#).

`hmac.new(key[, msg[, digestmod]])`

Return a new hmac object. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest constructor or module for the HMAC object to use. It defaults to the `hashlib.md5` constructor.

An HMAC object has the following methods:

`HMAC.update(msg)`

Update the hmac object with the string *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

`HMAC.digest()`

Return the digest of the strings passed to the `update()` method so far. This string will be the same length as the *digest_size* of the digest given to the constructor. It may contain non-ASCII characters, including NUL bytes.

Warning: When comparing the output of `digest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.hexdigest()`

Like `digest()` except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

Warning: When comparing the output of `hexdigest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.copy()`

Return a copy (“clone”) of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

This module also provides the following helper function:

`hmac.compare_digest(a, b)`

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either *unicode* or a *bytes-like object*.

Note: If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

New in version 2.7.7.

See also:

Module [hashlib](#) The Python module providing secure hash functions.

14.3 md5 — MD5 message digest algorithm

Deprecated since version 2.5: Use the [hashlib](#) module instead.

This module implements the interface to RSA’s MD5 message digest algorithm (see also Internet [RFC 1321](#)). Its use is quite straightforward: use `new()` to create an md5 object. You can now feed this object with arbitrary strings using the `update()` method, and at any point you can ask it for the *digest* (a strong kind of 128-bit checksum, a.k.a. “fingerprint”) of the concatenation of the strings fed to it so far using the `digest()` method.

For example, to obtain the digest of the string 'Nobody inspects the spammish repetition':

```
>>> import md5
>>> m = md5.new()
>>> m.update("Nobody inspects")
>>> m.update(" the spammish repetition")
>>> m.digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

More condensed:

```
>>> md5.new("Nobody inspects the spammish repetition").digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

The following values are provided as constants in the module and as attributes of the md5 objects returned by `new()`:

`md5.digest_size`

The size of the resulting digest in bytes. This is always 16.

The md5 module provides the following functions:

`md5.new([arg])`

Return a new md5 object. If *arg* is present, the method call `update(arg)` is made.

`md5.md5([arg])`

For backward compatibility reasons, this is an alternative name for the `new()` function.

An md5 object has the following methods:

`md5.update(arg)`

Update the md5 object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

`md5.digest()`

Return the digest of the strings passed to the `update()` method so far. This is a 16-byte string which may contain non-ASCII characters, including null bytes.

`md5.hexdigest()`

Like `digest()` except the digest is returned as a string of length 32, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`md5.copy()`

Return a copy (“clone”) of the md5 object. This can be used to efficiently compute the digests of strings that share a common initial substring.

See also:

Module [sha](#) Similar module implementing the Secure Hash Algorithm (SHA). The SHA algorithm is considered a more secure hash.

14.4 sha — SHA-1 message digest algorithm

Deprecated since version 2.5: Use the `hashlib` module instead.

This module implements the interface to NIST's secure hash algorithm, known as SHA-1. SHA-1 is an improved version of the original SHA hash algorithm. It is used in the same way as the `md5` module: use `new()` to create an sha object, then feed this object with arbitrary strings using the `update()` method, and at any point you can ask it for the `digest` of the concatenation of the strings fed to it so far. SHA-1 digests are 160 bits instead of MD5's 128 bits.

`sha.new([string])`

Return a new sha object. If *string* is present, the method call `update(string)` is made.

The following values are provided as constants in the module and as attributes of the sha objects returned by `new()`:

`sha.blocksize`

Size of the blocks fed into the hash function; this is always 1. This size is used to allow an arbitrary string to be hashed.

`sha.digest_size`

The size of the resulting digest in bytes. This is always 20.

An sha object has the same methods as md5 objects:

`sha.update(arg)`

Update the sha object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

`sha.digest()`

Return the digest of the strings passed to the `update()` method so far. This is a 20-byte string which may contain non-ASCII characters, including null bytes.

`sha.hexdigest()`

Like `digest()` except the digest is returned as a string of length 40, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`sha.copy()`

Return a copy ("clone") of the sha object. This can be used to efficiently compute the digests of strings that share a common initial substring.

Cryptographic Toolkit (Secure Hashing) [Links from NIST to various information on secure hashing.](#)

GENERIC OPERATING SYSTEM SERVICES

The modules described in this chapter provide interfaces to operating system features that are available on (almost) all operating systems, such as files and a clock. The interfaces are generally modeled after the Unix or C interfaces, but they are available on most other systems as well. Here's an overview:

15.1 `os` — Miscellaneous operating system interfaces

This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see `open()`, if you want to manipulate paths, see the `os.path` module, and if you want to read all the lines in all the files on the command line see the `fileinput` module. For creating temporary files and directories see the `tempfile` module, and for high-level file and directory handling see the `shutil` module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about `path` in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the `os` module, but using them is of course a threat to portability.
- An “Availability: Unix” note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim “Availability: Unix” are supported on Mac OS X, which builds on a Unix core.

Note: All functions in this module raise `OSError` in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.

exception `os.error`

An alias for the built-in `OSError` exception.

`os.name`

The name of the operating system dependent module imported. The following names have currently been registered: 'posix', 'nt', 'os2', 'ce', 'java', 'riscos'.

See also:

`sys.platform` has a finer granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

15.1.1 Process Parameters

These functions and data items provide information and operate on the current process and user.

`os.environ`

A *mapping* object representing the string environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the `os` module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in `os.environ`, except for changes made by modifying `os.environ` directly.

If the platform supports the `putenv()` function, this mapping may be used to modify the environment as well as query the environment. `putenv()` will be called automatically when the mapping is modified.

Note: Calling `putenv()` directly does not change `os.environ`, so it's better to modify `os.environ`.

Note: On some platforms, including FreeBSD and Mac OS X, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

If `putenv()` is not provided, a modified copy of this mapping may be passed to the appropriate process-creation functions to cause child processes to use a modified environment.

If the platform supports the `unsetenv()` function, you can delete items in this mapping to unset environment variables. `unsetenv()` will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

Changed in version 2.6: Also unset environment variables when calling `os.environ.clear()` and `os.environ.pop()`.

`os.chdir(path)`

`os.fchdir(fd)`

`os.getcwd()`

These functions are described in *Files and Directories*.

`os.ctermid()`

Return the filename corresponding to the controlling terminal of the process.

Availability: Unix.

`os.getegid()`

Return the effective group id of the current process. This corresponds to the “set id” bit on the file being executed in the current process.

Availability: Unix.

`os.geteuid()`

Return the current process's effective user id.

Availability: Unix.

`os.getgid()`

Return the real group id of the current process.

Availability: Unix.

`os.getgroups()`

Return list of supplemental group ids associated with the current process.

Availability: Unix.

Note: On Mac OS X, `getgroups()` behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of 10.5 or earlier, `getgroups()` returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to `setgroups()` if suitably privileged. If built with a deployment target greater than 10.5, `getgroups()` returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to `setgroups()`, and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with `sysconfig.get_config_var()`.

`os.initgroups(username, gid)`

Call the system `initgroups()` to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix.

New in version 2.7.

`os.getlogin()`

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use the environment variable `LOGNAME` to find out who the user is, or `pwd.getpwuid(os.getuid())[0]` to get the login name of the process's real user id.

Availability: Unix.

`os.getpgid(pid)`

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

Availability: Unix.

New in version 2.3.

`os.getpgrp()`

Return the id of the current process group.

Availability: Unix.

`os.getpid()`

Return the current process id.

Availability: Unix, Windows.

`os.getppid()`

Return the parent's process id.

Availability: Unix.

`os.getresuid()`

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

Availability: Unix.

New in version 2.7.

`os.getresgid()`

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

Availability: Unix.

New in version 2.7.

`os.getuid()`

Return the current process's real user id.

Availability: Unix.

`os.getenv(varname[, value])`

Return the value of the environment variable *varname* if it exists, or *value* if it doesn't. *value* defaults to `None`.

Availability: most flavors of Unix, Windows.

`os.putenv(varname, value)`

Set the environment variable named *varname* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Availability: most flavors of Unix, Windows.

Note: On some platforms, including FreeBSD and Mac OS X, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv`.

When `putenv()` is supported, assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however, calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`.

`os.setegid(egid)`

Set the current process's effective group id.

Availability: Unix.

`os.seteuid(euid)`

Set the current process's effective user id.

Availability: Unix.

`os.setgid(gid)`

Set the current process' group id.

Availability: Unix.

`os.setgroups(groups)`

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix.

New in version 2.2.

Note: On Mac OS X, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for `getgroups()` for cases where it may not return the same group list set by calling `setgroups()`.

`os.setpgrp()`

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix.

`os.setpgid(pid, pgrp)`

Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

Availability: Unix.

`os.setregid(rgid, egid)`

Set the current process's real and effective group ids.

Availability: Unix.

`os.setresgid(rgid, egid, sgid)`

Set the current process's real, effective, and saved group ids.

Availability: Unix.

New in version 2.7.

`os.setresuid(ruid, euid, suid)`

Set the current process's real, effective, and saved user ids.

Availability: Unix.

New in version 2.7.

`os.setreuid(ruid, euid)`

Set the current process's real and effective user ids.

Availability: Unix.

`os.getsid(pid)`

Call the system call `getsid()`. See the Unix manual for the semantics.

Availability: Unix.

New in version 2.4.

`os.setsid()`

Call the system call `setsid()`. See the Unix manual for the semantics.

Availability: Unix.

`os.setuid(uid)`

Set the current process's user id.

Availability: Unix.

`os.strerror(code)`

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, `ValueError` is raised.

Availability: Unix, Windows.

`os.umask(mask)`

Set the current numeric umask and return the previous umask.

Availability: Unix, Windows.

`os.uname()`

Return a 5-tuple containing information identifying the current operating system. The tuple contains 5 strings: (*sysname*, *nodename*, *release*, *version*, *machine*). Some systems truncate the *nodename* to 8 characters or to the leading component; a better way to get the hostname is `socket.gethostname()` or even `socket.gethostbyaddr(socket.gethostname())`.

Availability: recent flavors of Unix.

`os.unsetenv(varname)`

Unset (delete) the environment variable named *varname*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

When `unsetenv()` is supported, deletion of items in `os.environ` is automatically translated into a corresponding call to `unsetenv()`; however, calls to `unsetenv()` don't update `os.environ`, so it is actually preferable to delete items of `os.environ`.

Availability: most flavors of Unix, Windows.

15.1.2 File Object Creation

These functions create new file objects. (See also `open()`.)

`os.fopen(fd [, mode [, bufsize]])`

Return an open file object connected to the file descriptor *fd*. The *mode* and *bufsize* arguments have the same meaning as the corresponding arguments to the built-in `open()` function. If `fopen()` raises an exception, it leaves *fd* untouched (unclosed).

Availability: Unix, Windows.

Changed in version 2.3: When specified, the *mode* argument must now start with one of the letters 'r', 'w', or 'a', otherwise a `ValueError` is raised.

Changed in version 2.5: On Unix, when the *mode* argument starts with 'a', the `O_APPEND` flag is set on the file descriptor (which the `fopen()` implementation already does on most platforms).

`os.popen(command [, mode [, bufsize]])`

Open a pipe to or from *command*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *bufsize* argument has the same meaning as the corresponding argument to the built-in `open()` function. The exit status of the command (encoded in the format specified for `wait()`) is available as the return value of the `close()` method of the file object, except that when the exit status is zero (termination without errors), None is returned.

Availability: Unix, Windows.

Deprecated since version 2.6: This function is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

Changed in version 2.0: This function worked unreliably under Windows in earlier versions of Python. This was due to the use of the `_popen()` function from the libraries provided with Windows. Newer versions of Python do not use the broken implementation from the Windows libraries.

`os.tmpfile()`

Return a new file object opened in update mode (`w+b`). The file has no directory entries associated with it and will be automatically deleted once there are no file descriptors for the file.

Availability: Unix, Windows.

There are a number of different `popen*`() functions that provide slightly different ways to create subprocesses.

Deprecated since version 2.6: All of the `popen*`() functions are obsolete. Use the `subprocess` module.

For each of the `popen*`() variants, if *bufsize* is specified, it specifies the buffer size for the I/O pipes. *mode*, if provided, should be the string 'b' or 't'; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for *mode* is 't'.

Also, for each of these variants, on Unix, *cmd* may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If *cmd* is a string it will be passed to the shell (as with `os.system()`).

These methods do not make it possible to retrieve the exit status from the child processes. The only way to control the input and output streams and also retrieve the return codes is to use the `subprocess` module; these are only available on Unix.

For a discussion of possible deadlock conditions related to the use of these functions, see [Flow Control Issues](#).

`os.popen2(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child_stdin*, *child_stdout*).

Deprecated since version 2.6: This function is obsolete. Use the [subprocess](#) module. Check especially the [Replacing Older Functions with the subprocess Module](#) section.

Availability: Unix, Windows.

New in version 2.0.

`os.popen3(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child_stdin*, *child_stdout*, *child_stderr*).

Deprecated since version 2.6: This function is obsolete. Use the [subprocess](#) module. Check especially the [Replacing Older Functions with the subprocess Module](#) section.

Availability: Unix, Windows.

New in version 2.0.

`os.popen4(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child_stdin*, *child_stdout_and_stderr*).

Deprecated since version 2.6: This function is obsolete. Use the [subprocess](#) module. Check especially the [Replacing Older Functions with the subprocess Module](#) section.

Availability: Unix, Windows.

New in version 2.0.

(Note that *child_stdin*, *child_stdout*, and *child_stderr* are named from the point of view of the child process, so *child_stdin* is the child's standard input.)

This functionality is also available in the [popen2](#) module using functions of the same names, but the return values of those functions have a different order.

15.1.3 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name “file descriptor” is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The [fileno\(\)](#) method can be used to obtain the file descriptor associated with a file object when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

`os.close(fd)`

Close file descriptor *fd*.

Availability: Unix, Windows.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by [os.open\(\)](#) or [pipe\(\)](#). To close a “file object” returned by the built-in function [open\(\)](#) or by [popen\(\)](#) or [fdopen\(\)](#), use its [close\(\)](#) method.

`os.closerange` (*fd_low*, *fd_high*)

Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to:

```
for fd in xrange(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

Availability: Unix, Windows.

New in version 2.6.

`os.dup` (*fd*)

Return a duplicate of file descriptor *fd*.

Availability: Unix, Windows.

`os.dup2` (*fd*, *fd2*)

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary.

Availability: Unix, Windows.

`os.fchmod` (*fd*, *mode*)

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for `chmod()` for possible values of *mode*.

Availability: Unix.

New in version 2.6.

`os.fchown` (*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

Availability: Unix.

New in version 2.6.

`os.fdatasync` (*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

Availability: Unix.

Note: This function is not available on MacOS.

`os.fpathconf` (*fd*, *name*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix.

`os.fstat` (*fd*)

Return status for file descriptor *fd*, like `stat()`.

Availability: Unix, Windows.

os.fstatvfs(*fd*)

Return information about the filesystem containing the file associated with file descriptor *fd*, like *statvfs()*.

Availability: Unix.

os.fsync(*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native *fsync()* function; on Windows, the *MS_commit()* function.

If you're starting with a Python file object *f*, first do *f.flush()*, and then do *os.fsync(f.fileno())*, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, and Windows starting in 2.2.3.

os.ftruncate(*fd*, *length*)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size.

Availability: Unix.

os.isatty(*fd*)

Return *True* if the file descriptor *fd* is open and connected to a tty(-like) device, else *False*.

os.lseek(*fd*, *pos*, *how*)

Set the current position of file descriptor *fd* to position *pos*, modified by *how*: *SEEK_SET* or 0 to set the position relative to the beginning of the file; *SEEK_CUR* or 1 to set it relative to the current position; *SEEK_END* or 2 to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

Availability: Unix, Windows.

os.SEEK_SET

os.SEEK_CUR

os.SEEK_END

Parameters to the *lseek()* function. Their values are 0, 1, and 2, respectively.

Availability: Windows, Unix.

New in version 2.5.

os.open(*file*, *flags*[, *mode*])

Open the file *file* and set various flags according to *flags* and possibly its mode according to *mode*. The default *mode* is 0777 (octal), and the current umask value is first masked out. Return the file descriptor for the newly opened file.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like *O_RDONLY* and *O_WRONLY*) are defined in this module too (see *open() flag constants*). In particular, on Windows adding *O_BINARY* is needed to open files in binary mode.

Availability: Unix, Windows.

Note: This function is intended for low-level I/O. For normal usage, use the built-in function *open()*, which returns a “file object” with *read()* and *write()* methods (and many more). To wrap a file descriptor in a “file object”, use *fdopen()*.

os.openpty()

Open a new pseudo-terminal pair. Return a pair of file descriptors (*master*, *slave*) for the pty and the tty, respectively. For a (slightly) more portable approach, use the *pty* module.

Availability: some flavors of Unix.

`os.pipe()`

Create a pipe. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively.

Availability: Unix, Windows.

`os.read(fd, n)`

Read at most `n` bytes from file descriptor `fd`. Return a string containing the bytes read. If the end of the file referred to by `fd` has been reached, an empty string is returned.

Availability: Unix, Windows.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

`os.tcgetpgrp(fd)`

Return the process group associated with the terminal given by `fd` (an open file descriptor as returned by `os.open()`).

Availability: Unix.

`os.tcsetpgrp(fd, pg)`

Set the process group associated with the terminal given by `fd` (an open file descriptor as returned by `os.open()`) to `pg`.

Availability: Unix.

`os.ttyname(fd)`

Return a string which specifies the terminal device associated with file descriptor `fd`. If `fd` is not associated with a terminal device, an exception is raised.

Availability: Unix.

`os.write(fd, str)`

Write the string `str` to file descriptor `fd`. Return the number of bytes actually written.

Availability: Unix, Windows.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To write a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdout` or `sys.stderr`, use its `write()` method.

`open()` flag constants

The following constants are options for the `flags` parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the `open(2)` manual page on Unix or the [MSDN](#) on Windows.

`os.O_RDONLY`

`os.O_WRONLY`

`os.O_RDWR`

`os.O_APPEND`

`os.O_CREAT`

`os.O_EXCL`

`os.O_TRUNC`

The above constants are available on Unix and Windows.

```

os.O_DSYNC
os.O_RSYNC
os.O_SYNC
os.O_NDELAY
os.O_NONBLOCK
os.O_NOCTTY

```

The above constants are only available on Unix.

```

os.O_BINARY
os.O_NOINHERIT
os.O_SHORT_LIVED
os.O_TEMPORARY
os.O_RANDOM
os.O_SEQUENTIAL
os.O_TEXT

```

The above constants are only available on Windows.

```

os.O_ASYNC
os.O_DIRECT
os.O_DIRECTORY
os.O_NOFOLLOW
os.O_NOATIME
os.O_SHLOCK
os.O_EXLOCK

```

The above constants are extensions and not present if they are not defined by the C library.

15.1.4 Files and Directories

`os.access(path, mode)`

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be `F_OK` to test the existence of *path*, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page `access(2)` for more information.

Availability: Unix, Windows.

Note: Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```

if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"

```

is better written as:

```

try:
    fp = open("myfile")
except IOError as e:
    if e.errno == errno.EACCES:
        return "some default data"
    # Not a permission error.

```

(continues on next page)

(continued from previous page)

```
    raise
else:
    with fp:
        return fp.read()
```

Note: I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

os.**F_OK**

Value to pass as the *mode* parameter of `access()` to test the existence of *path*.

os.**R_OK**

Value to include in the *mode* parameter of `access()` to test the readability of *path*.

os.**W_OK**

Value to include in the *mode* parameter of `access()` to test the writability of *path*.

os.**X_OK**

Value to include in the *mode* parameter of `access()` to determine if *path* can be executed.

os.**chdir** (*path*)

Change the current working directory to *path*.

Availability: Unix, Windows.

os.**fchdir** (*fd*)

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file.

Availability: Unix.

New in version 2.3.

os.**getcwd** ()

Return a string representing the current working directory.

Availability: Unix, Windows.

os.**getcwdu** ()

Return a Unicode object representing the current working directory.

Availability: Unix, Windows.

New in version 2.3.

os.**chflags** (*path*, *flags*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`

- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

Availability: Unix.

New in version 2.6.

`os.chroot(path)`

Change the root directory of the current process to *path*. Availability: Unix.

New in version 2.2.

`os.chmod(path, mode)`

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the `stat` module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IREAD`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`
- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

Availability: Unix, Windows.

Note: Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

- `os.chown(path, uid, gid)`
 Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.
 Availability: Unix.
- `os.lchflags(path, flags)`
 Set the flags of *path* to the numeric *flags*, like `chflags()`, but do not follow symbolic links.
 Availability: Unix.
 New in version 2.6.
- `os.lchmod(path, mode)`
 Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of *mode*.
 Availability: Unix.
 New in version 2.6.
- `os.lchown(path, uid, gid)`
 Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links.
 Availability: Unix.
 New in version 2.3.
- `os.link(source, link_name)`
 Create a hard link pointing to *source* named *link_name*.
 Availability: Unix.
- `os.listdir(path)`
 Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order. It does not include the special entries `'.'` and `'..'` even if they are present in the directory.
 Availability: Unix, Windows.
 Changed in version 2.3: On Windows NT/2k/XP and Unix, if *path* is a Unicode object, the result will be a list of Unicode objects. Undecodable filenames will still be returned as string objects.
- `os.lstat(path)`
 Perform the equivalent of an `lstat()` system call on the given path. Similar to `stat()`, but does not follow symbolic links. On platforms that do not support symbolic links, this is an alias for `stat()`.
- `os.mkfifo(path[, mode])`
 Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The default *mode* is 0666 (octal). The current umask value is first masked out from the mode.
 Availability: Unix.
 FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between “client” and “server” type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn’t open the FIFO — it just creates the rendezvous point.
- `os.mknod(filename[, mode=0600[, device=0]])`
 Create a filesystem node (file, device special file or named pipe) named *filename*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.
 New in version 2.3.

os.major (*device*)

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

New in version 2.3.

os.minor (*device*)

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

New in version 2.3.

os.makedev (*major*, *minor*)

Compose a raw device number from the major and minor device numbers.

New in version 2.3.

os.mkdir (*path*[, *mode*])

Create a directory named *path* with numeric mode *mode*. The default *mode* is 0777 (octal). If the directory already exists, `OSError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

Availability: Unix, Windows.

os.makedirs (*path*[, *mode*])

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory. Raises an `error` exception if the leaf directory already exists or cannot be created. The default *mode* is 0777 (octal).

The *mode* parameter is passed to `mkdir()`; see [the mkdir\(\) description](#) for how it is interpreted.

Note: `makedirs()` will become confused if the path elements to create include `os.pardir`.

New in version 1.5.2.

Changed in version 2.3: This function now handles UNC paths correctly.

os.pathconf (*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix.

os.pathconf_names

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system. Availability: Unix.

os.readlink (*path*)

Return a string representing the path to which the symbolic link points. The result may be either an absolute or

relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

Changed in version 2.6: If the *path* is a Unicode object the result will also be a Unicode object.

Availability: Unix.

`os.remove(path)`

Remove (delete) the file *path*. If *path* is a directory, `OSError` is raised; see `rmdir()` below to remove a directory. This is identical to the `unlink()` function documented below. On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

Availability: Unix, Windows.

`os.removedirs(path)`

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory 'foo/bar/baz', and then remove 'foo/bar' and 'foo' if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

New in version 1.5.2.

`os.rename(src, dst)`

Rename the file or directory *src* to *dst*. If *dst* is a directory, `OSError` will be raised. On Unix, if *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement). On Windows, if *dst* already exists, `OSError` will be raised even if it is a file; there may be no way to implement an atomic rename when *dst* names an existing file.

Availability: Unix, Windows.

`os.rename(old, new)`

Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`.

New in version 1.5.2.

Note: This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

`os.rmdir(path)`

Remove (delete) the directory *path*. Only works when the directory is empty, otherwise, `OSError` is raised. In order to remove whole directory trees, `shutil.rmtree()` can be used.

Availability: Unix, Windows.

`os.stat(path)`

Perform the equivalent of a `stat()` system call on the given path. (This function follows symlinks; to stat a symlink use `lstat()`.)

The return value is an object whose attributes correspond to the members of the `stat` structure, namely:

- `st_mode` - protection bits,
- `st_ino` - inode number,
- `st_dev` - device,

- `st_nlink` - number of hard links,
- `st_uid` - user id of owner,
- `st_gid` - group id of owner,
- `st_size` - size of file, in bytes,
- `st_atime` - time of most recent access,
- `st_mtime` - time of most recent content modification,
- `st_ctime` - platform dependent; time of most recent metadata change on Unix, or the time of creation on Windows)

Changed in version 2.3: If `stat_float_times()` returns `True`, the time values are floats, measuring seconds. Fractions of a second may be reported if the system supports that. See `stat_float_times()` for further discussion.

On some Unix systems (such as Linux), the following attributes may also be available:

- `st_blocks` - number of 512-byte blocks allocated for file
- `st_blksize` - filesystem blocksize for efficient file system I/O
- `st_rdev` - type of device if an inode device
- `st_flags` - user defined flags for file

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

- `st_gen` - file generation number
- `st_birthtime` - time of file creation

On RISCOS systems, the following attributes are also available:

- `st_ftime` (file type)
- `st_attrs` (attributes)
- `st_obtype` (object type).

Note: The exact meaning and resolution of the `st_atime`, `st_mtime`, and `st_ctime` attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, `st_mtime` has 2-second resolution, and `st_atime` has only 1-day resolution. See your operating system documentation for details.

For backward compatibility, the return value of `stat()` is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations.

The standard module `stat` defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
(33188, 422511, 769, 1, 1032, 100, 926, 1105022698, 1105022732, 1105022732)
```

(continues on next page)

(continued from previous page)

```
>>> statinfo.st_size
926
```

Availability: Unix, Windows.

Changed in version 2.2: Added access to values as attributes of the returned object.

Changed in version 2.5: Added `st_gen` and `st_birthtime`.

`os.stat_float_times([newvalue])`

Determine whether `stat_result` represents time stamps as float objects. If `newvalue` is `True`, future calls to `stat()` return floats, if it is `False`, future calls return ints. If `newvalue` is omitted, return the current setting.

For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

Changed in version 2.5: Python now returns float values by default. Applications which do not work correctly with floating point time stamps can use this function to restore the old behaviour.

The resolution of the timestamps (that is the smallest possible fraction) depends on the system. Some systems only support second resolution; on these systems, the fraction will always be zero.

It is recommended that this setting is only changed at program startup time in the `__main__` module; libraries should never change this setting. If an application uses a library that works incorrectly if floating point time stamps are processed, this application should turn the feature off until the library has been corrected.

`os.statvfs(path)`

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`.

For backward compatibility, the return value is also accessible as a tuple whose values correspond to the attributes, in the order given above. The standard module `statvfs` defines constants that are useful for extracting information from a `statvfs` structure when accessing it as a sequence; this remains useful when writing code that needs to work with versions of Python that don't support accessing the fields as attributes.

Availability: Unix.

Changed in version 2.2: Added access to values as attributes of the returned object.

`os.symlink(source, link_name)`

Create a symbolic link pointing to `source` named `link_name`.

Availability: Unix.

`os.tempnam([dir[, prefix]])`

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in the directory `dir` or a common location for temporary files if `dir` is omitted or `None`. If given and not `None`, `prefix` is used to provide a short prefix to the filename. Applications are responsible for properly creating and managing files created using paths returned by `tempnam()`; no automatic cleanup is provided. On Unix, the environment variable `TMPDIR` overrides `dir`, while on Windows `TMP` is used. The specific behavior of this function depends on the C library implementation; some aspects are underspecified in system documentation.

Warning: Use of `tempnam()` is vulnerable to symlink attacks; consider using `tmpfile()` (section [File Object Creation](#)) instead.

Availability: Unix, Windows.

os.tmpnam()

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in a common location for temporary files. Applications are responsible for properly creating and managing files created using paths returned by `tmpnam()`; no automatic cleanup is provided.

Warning: Use of `tmpnam()` is vulnerable to symlink attacks; consider using `tempfile()` (section [File Object Creation](#)) instead.

Availability: Unix, Windows. This function probably shouldn't be used on Windows, though: Microsoft's implementation of `tmpnam()` always creates a name in the root directory of the current drive, and that's generally a poor location for a temp file (depending on privileges, you may not even be able to open a file using this name).

os.TMP_MAX

The maximum number of unique names that `tmpnam()` will generate before reusing names.

os.unlink(path)

Remove (delete) the file *path*. This is the same function as `remove()`; the `unlink()` name is its traditional Unix name.

Availability: Unix, Windows.

os.utime(path, times)

Set the access and modified times of the file specified by *path*. If *times* is `None`, then the file's access and modified times are set to the current time. (The effect is similar to running the Unix program `touch` on the path.) Otherwise, *times* must be a 2-tuple of numbers, of the form `(atime, mtime)` which is used to set the access and modified times, respectively. Whether a directory can be given for *path* depends on whether the operating system implements directories as files (for example, Windows does not). Note that the exact times you set here may not be returned by a subsequent `stat()` call, depending on the resolution with which your operating system records access and modification times; see `stat()`.

Changed in version 2.0: Added support for `None` for *times*.

Availability: Unix, Windows.

os.walk(top, topdown=True, onerror=None, followlinks=False)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and `walk()` will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform `walk()` about directories the caller creates or renames before it resumes `walk()` again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the `listdir()` call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an `OSError` instance. It can report the error to continue with the

walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, `walk()` will not walk down into symbolic links that resolve to directories. Set `followlinks` to `True` to visit directories pointed to by symlinks, on systems that support them.

New in version 2.6: The `followlinks` parameter.

Note: Be aware that setting `followlinks` to `True` can lead to infinite recursion if a link points to a parent directory of itself. `walk()` does not keep track of the directories it visited already.

Note: If you pass a relative pathname, don't change the current working directory between resumptions of `walk()`. `walk()` never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print root, "consumes",
    print sum(getsize(join(root, name)) for name in files),
    print "bytes in", len(files), "non-directory files"
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

New in version 2.3.

15.1.5 Process Management

These functions may be used to create and manage processes.

The various `exec*` functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

`os.abort()`

Generate a SIGABRT signal to the current process. On Unix, the default behavior is to produce a core dump; on

Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for SIGABRT with `signal.signal()`.

Availability: Unix, Windows.

```
os.exec1(path, arg0, arg1, ...)
os.execl(path, arg0, arg1, ..., env)
os.execlp(file, arg0, arg1, ...)
os.execlpe(file, arg0, arg1, ..., env)
os.execv(path, args)
os.execve(path, args, env)
os.execvp(file, args)
os.execvpe(file, args, env)
```

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as `OSError` exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or `os.fsync()` before calling an `exec*` function.

The “l” and “v” variants of the `exec*` functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `exec1*`() functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the `args` parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a “p” near the end (`execlp()`, `execlpe()`, `execvp()`, and `execvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `exec*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `execl()`, `execlpe()`, `execv()`, and `execve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `execlpe()`, `execlpe()`, `execve()`, and `execvpe()` (note that these all end in “e”), the `env` parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process’ environment); the functions `execl()`, `execlp()`, `execv()`, and `execvp()` all cause the new process to inherit the environment of the current process.

Availability: Unix, Windows.

```
os._exit(n)
```

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

Availability: Unix, Windows.

Note: The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server’s external command delivery program.

Note: Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

- **os.EX_OK**
Exit code that means no error occurred.
Availability: Unix.
New in version 2.3.
- **os.EX_USAGE**
Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.
Availability: Unix.
New in version 2.3.
- **os.EX_DATAERR**
Exit code that means the input data was incorrect.
Availability: Unix.
New in version 2.3.
- **os.EX_NOINPUT**
Exit code that means an input file did not exist or was not readable.
Availability: Unix.
New in version 2.3.
- **os.EX_NOUSER**
Exit code that means a specified user did not exist.
Availability: Unix.
New in version 2.3.
- **os.EX_NOHOST**
Exit code that means a specified host did not exist.
Availability: Unix.
New in version 2.3.
- **os.EX_UNAVAILABLE**
Exit code that means that a required service is unavailable.
Availability: Unix.
New in version 2.3.
- **os.EX_SOFTWARE**
Exit code that means an internal software error was detected.
Availability: Unix.
New in version 2.3.
- **os.EX_OSERR**
Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.
Availability: Unix.
New in version 2.3.
- **os.EX_OSFILE**
Exit code that means some system file did not exist, could not be opened, or had some other kind of error.
Availability: Unix.

New in version 2.3.

os.EX_CANTCREAT

Exit code that means a user specified output file could not be created.

Availability: Unix.

New in version 2.3.

os.EX_IOERR

Exit code that means that an error occurred while doing I/O on some file.

Availability: Unix.

New in version 2.3.

os.EX_TEMPFAIL

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

Availability: Unix.

New in version 2.3.

os.EX_PROTOCOL

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

Availability: Unix.

New in version 2.3.

os.EX_NOPERM

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

Availability: Unix.

New in version 2.3.

os.EX_CONFIG

Exit code that means that some kind of configuration error occurred.

Availability: Unix.

New in version 2.3.

os.EX_NOTFOUND

Exit code that means something like “an entry was not found”.

Availability: Unix.

New in version 2.3.

os.fork()

Fork a child process. Return 0 in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3, Cygwin and OS/2 EMX have known issues when using fork() from a thread.

Warning: See [ssl](#) for applications that use the SSL module with fork().

Availability: Unix.

`os.forkpty()`

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of (`pid`, `fd`), where `pid` is 0 in the child, the new child's process id in the parent, and `fd` is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the `pty` module. If an error occurs `OSError` is raised.

Availability: some flavors of Unix.

`os.kill(pid, sig)`

Send signal `sig` to the process `pid`. Constants for the specific signals available on the host platform are defined in the `signal` module.

Windows: The `signal.CTRL_C_EVENT` and `signal.CTRL_BREAK_EVENT` signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for `sig` will cause the process to be unconditionally killed by the `TerminateProcess` API, and the exit code will be set to `sig`. The Windows version of `kill()` additionally takes process handles to be killed.

New in version 2.7: Windows support

`os.killpg(pgid, sig)`

Send the signal `sig` to the process group `pgid`.

Availability: Unix.

New in version 2.3.

`os.nice(increment)`

Add `increment` to the process's "niceness". Return the new niceness.

Availability: Unix.

`os.lock(op)`

Lock program segments into memory. The value of `op` (defined in `<sys/lock.h>`) determines which segments are locked.

Availability: Unix.

`os.popen(...)`

`os.popen2(...)`

`os.popen3(...)`

`os.popen4(...)`

Run child processes, returning opened pipes for communications. These functions are described in section [File Object Creation](#).

`os.spawnl(mode, path, ...)`

`os.spawnle(mode, path, ..., env)`

`os.spawnlp(mode, file, ...)`

`os.spawnlpe(mode, file, ..., env)`

`os.spawnv(mode, path, args)`

`os.spawnve(mode, path, args, env)`

`os.spawnvp(mode, file, args)`

`os.spawnvpe(mode, file, args, env)`

Execute the program `path` in a new process.

(Note that the `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the [Replacing Older Functions with the subprocess Module](#) section.)

If `mode` is `P_NOWAIT`, this function returns the process id of the new process; if `mode` is `P_WAIT`, returns the process's exit code if it exits normally, or `-signal`, where `signal` is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the `waitpid()` function.

The “l” and “v” variants of the *spawn** functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the *spawnl**() functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second “p” near the end (*spawnlp*(), *spawnlpe*(), *spawnvp*(), and *spawnvpe*()) will use the *PATH* environment variable to locate the program *file*. When the environment is being replaced (using one of the *spawn*e* variants, discussed in the next paragraph), the new environment is used as the source of the *PATH* variable. The other variants, *spawnl*(), *spawnle*(), *spawnv*(), and *spawnve*(), will not use the *PATH* variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For *spawnle*(), *spawnlpe*(), *spawnve*(), and *spawnvpe*() (note that these all end in “e”), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process’ environment); the functions *spawnl*(), *spawnlp*(), *spawnv*(), and *spawnvp*() all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to *spawnlp*() and *spawnvpe*() are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Availability: Unix, Windows. *spawnlp*(), *spawnlpe*(), *spawnvp*() and *spawnvpe*() are not available on Windows. *spawnle*() and *spawnve*() are not thread-safe on Windows; we advise you to use the *subprocess* module instead.

New in version 1.6.

os.P_NOWAIT

os.P_NOWAITO

Possible values for the *mode* parameter to the *spawn** family of functions. If either of these values is given, the *spawn**() functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

New in version 1.6.

os.P_WAIT

Possible value for the *mode* parameter to the *spawn** family of functions. If this is given as *mode*, the *spawn**() functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or *-signal* if a signal kills the process.

Availability: Unix, Windows.

New in version 1.6.

os.P_DETACH

os.P_OVERLAY

Possible values for the *mode* parameter to the *spawn** family of functions. These are less portable than those listed above. *P_DETACH* is similar to *P_NOWAIT*, but the new process is detached from the console of the calling process. If *P_OVERLAY* is used, the current process will be replaced; the *spawn**() function will not return.

Availability: Windows.

New in version 1.6.

os.startfile (*path* [, *operation*])

Start a file with its associated application.

When *operation* is not specified or 'open', this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the **start** command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a “command verb” that specifies what should be done with the file. Common verbs documented by Microsoft are 'print' and 'edit' (to be used on files) as well as 'explore' and 'find' (to be used on directories).

startfile() returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application’s exit status. The *path* parameter is relative to the current directory. If you want to use an absolute path, make sure the first character is not a slash ('/'); the underlying Win32 `ShellExecute()` function doesn’t work if it is. Use the *os.path.normpath()* function to ensure that the path is properly encoded for Win32.

Availability: Windows.

New in version 2.0.

New in version 2.5: The *operation* parameter.

os.system (*command*)

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to *sys.stdin*, etc. are not reflected in the environment of the executed command.

On Unix, the return value is the exit status of the process encoded in the format specified for *wait()*. Note that POSIX does not specify the meaning of the return value of the C `system()` function, so the return value of the Python function is system-dependent.

On Windows, the return value is that returned by the system shell after running *command*, given by the Windows environment variable `COMSPEC`: on **command.com** systems (Windows 95, 98 and ME) this is always 0; on **cmd.exe** systems (Windows NT, 2000 and XP) this is the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the *Replacing Older Functions with the subprocess Module* section in the *subprocess* documentation for some helpful recipes.

Availability: Unix, Windows.

os.times ()

Return a 5-tuple of floating point numbers indicating accumulated (processor or other) times, in seconds. The items are: user time, system time, children’s user time, children’s system time, and elapsed real time since a fixed point in the past, in that order. See the Unix manual page *times(2)* or the corresponding Windows Platform API documentation. On Windows, only the first two items are filled, the others are zero.

Availability: Unix, Windows

os.wait ()

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

Availability: Unix.

os.waitpid (*pid*, *options*)

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for `wait()`). The semantics of the call are affected by the value of the integer *options*, which should be 0 for normal operation.

If *pid* is greater than 0, `waitpid()` requests status information for that specific process. If *pid* is 0, the request is for the status of any child in the process group of the current process. If *pid* is -1, the request pertains to any child of the current process. If *pid* is less than -1, status is requested for any process in the process group -*pid* (the absolute value of *pid*).

An `OSError` is raised with the value of `errno` when the syscall returns -1.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The `spawn*` functions called with `P_NOWAIT` return suitable process handles.

`os.wait3(options)`

Similar to `waitpid()`, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The option argument is the same as that provided to `waitpid()` and `wait4()`.

Availability: Unix.

New in version 2.5.

`os.wait4(pid, options)`

Similar to `waitpid()`, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The arguments to `wait4()` are the same as those provided to `waitpid()`.

Availability: Unix.

New in version 2.5.

`os.WNOHANG`

The option for `waitpid()` to return immediately if no child process status is available immediately. The function returns (0, 0) in this case.

Availability: Unix.

`os.WCONTINUED`

This option causes child processes to be reported if they have been continued from a job control stop since their status was last reported.

Availability: Some Unix systems.

New in version 2.3.

`os.WUNTRACED`

This option causes child processes to be reported if they have been stopped but their current state has not been reported since they were stopped.

Availability: Unix.

New in version 2.3.

The following functions take a process status code as returned by `system()`, `wait()`, or `waitpid()` as a parameter. They may be used to determine the disposition of a process.

`os.WCOREDUMP(status)`

Return `True` if a core dump was generated for the process, otherwise return `False`.

Availability: Unix.

New in version 2.3.

`os.WIFCONTINUED` (*status*)

Return `True` if the process has been continued from a job control stop, otherwise return `False`.

Availability: Unix.

New in version 2.3.

`os.WIFSTOPPED` (*status*)

Return `True` if the process has been stopped, otherwise return `False`.

Availability: Unix.

`os.WIFSIGNALED` (*status*)

Return `True` if the process exited due to a signal, otherwise return `False`.

Availability: Unix.

`os.WIFEXITED` (*status*)

Return `True` if the process exited using the `exit(2)` system call, otherwise return `False`.

Availability: Unix.

`os.WEXITSTATUS` (*status*)

If `WIFEXITED(status)` is true, return the integer parameter to the `exit(2)` system call. Otherwise, the return value is meaningless.

Availability: Unix.

`os.WSTOPSIG` (*status*)

Return the signal which caused the process to stop.

Availability: Unix.

`os.WTERMSIG` (*status*)

Return the signal which caused the process to exit.

Availability: Unix.

15.1.6 Miscellaneous System Information

`os.confstr` (*name*)

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix

`os.confstr_names`

Dictionary mapping names accepted by `confstr()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.getloadavg()`

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises `OSError` if the load average was unobtainable.

Availability: Unix.

New in version 2.3.

`os.sysconf(name)`

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for `confstr()` apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

`os.sysconf_names`

Dictionary mapping names accepted by `sysconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the `os.path` module.

`os.curdir`

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via `os.path`.

`os.pardir`

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via `os.path`.

`os.sep`

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use `os.path.split()` and `os.path.join()` — but it is occasionally useful. Also available via `os.path`.

`os.altsep`

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via `os.path`.

`os.extsep`

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via `os.path`.

New in version 2.2.

`os.pathsep`

The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or `';'` for Windows. Also available via `os.path`.

`os.defpath`

The default search path used by `exec*p*` and `spawn*p*` if the environment doesn't have a `'PATH'` key. Also available via `os.path`.

`os.linesep`

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use `os.linesep` as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

`os.devnull`

The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via `os.path`.

New in version 2.4.

15.1.7 Miscellaneous Functions

`os.urandom(n)`

Return a string of *n* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation. On a UNIX-like system this will query `/dev/urandom`, and on Windows it will use `CryptGenRandom()`. If a randomness source is not found, `NotImplementedError` will be raised.

For an easy-to-use interface to the random number generator provided by your platform, please see `random.SystemRandom`.

New in version 2.4.

15.2 `io` — Core tools for working with streams

New in version 2.6.

The `io` module provides the Python interfaces to stream handling. Under Python 2.x, this is proposed as an alternative to the built-in `file` object, but in Python 3.x it is the default interface to access files and streams.

Note: Since this module has been designed primarily for Python 3.x, you have to be aware that all uses of “bytes” in this document refer to the `str` type (of which `bytes` is an alias), and all uses of “text” refer to the `unicode` type. Furthermore, those two types are not interchangeable in the `io` APIs.

At the top of the I/O hierarchy is the abstract base class `IOBase`. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise an `IOError` if they do not support a given operation.

Extending `IOBase` is `RawIOBase` which deals simply with the reading and writing of raw bytes to a stream. `FileIO` subclasses `RawIOBase` to provide an interface to files in the machine’s file system.

`BufferedIOBase` deals with buffering on a raw byte stream (`RawIOBase`). Its subclasses, `BufferedWriter`, `BufferedReader`, and `BufferedRWPair` buffer streams that are readable, writable, and both readable and writable. `BufferedRandom` provides a buffered interface to random access streams. `BytesIO` is a simple stream of in-memory bytes.

Another `IOBase` subclass, `TextIOBase`, deals with streams whose bytes represent text, and handles encoding and decoding from and to `unicode` strings. `TextIOWrapper`, which extends it, is a buffered text interface to a buffered raw stream (`BufferedIOBase`). Finally, `StringIO` is an in-memory stream for unicode text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.

15.2.1 Module Interface

`io.DEFAULT_BUFFER_SIZE`

An int containing the default buffer size used by the module’s buffered I/O classes. `open()` uses the file’s `blksize` (as obtained by `os.stat()`) if possible.

`io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True)`

Open *file* and return a corresponding stream. If the file cannot be opened, an `IOError` is raised.

file is either a string giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed, unless *closefd* is set to `False`.)

mode is an optional string that specifies the mode in which the file is opened. It defaults to `'r'` which means open for reading in text mode. Other common values are `'w'` for writing (truncating the file if it already exists), and `'a'` for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform dependent. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are:

| Character | Meaning |
|------------------|---|
| <code>'r'</code> | open for reading (default) |
| <code>'w'</code> | open for writing, truncating the file first |
| <code>'a'</code> | open for writing, appending to the end of the file if it exists |
| <code>'b'</code> | binary mode |
| <code>'t'</code> | text mode (default) |
| <code>'+'</code> | open a disk file for updating (reading and writing) |
| <code>'U'</code> | universal newlines mode (for backwards compatibility; should not be used in new code) |

The default mode is `'rt'` (open for reading text). For binary random access, the mode `'w+b'` opens and truncates the file to 0 bytes, while `'r+b'` opens the file without truncation.

Python distinguishes between files opened in binary and text modes, even when the underlying operating system doesn’t. Files opened in binary mode (including `'b'` in the *mode* argument) return contents as `bytes` objects without any decoding. In text mode (the default, or when `'t'` is included in the *mode* argument), the contents of the file are returned as *unicode* strings, the bytes having been first decoded using a platform-dependent encoding or using the specified *encoding* if given.

buffering is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer > 1 to indicate the size of a fixed-size chunk buffer. When no *buffering* argument is given, the default buffering policy works as follows:

- Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device’s “block size” and falling back on `DEFAULT_BUFFER_SIZE`. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- “Interactive” text files (files for which `isatty()` returns `True`) use line buffering. Other text files use the policy described above for binary files.

encoding is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever `locale.getpreferredencoding()` returns), but any encoding supported by Python can be used. See the `codecs` module for the list of supported encodings.

errors is an optional string that specifies how encoding and decoding errors are to be handled—this cannot be used in binary mode. Pass `'strict'` to raise a `ValueError` exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference)

or `'backslashreplace'` (replace with backslashed escape sequences) can be used. Any other error handling name that has been registered with `codecs.register_error()` is also valid.

`newline` controls how *universal newlines* works (it only applies to text mode). It can be `None`, `' '`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- On input, if `newline` is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `' '`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- On output, if `newline` is `None`, any `'\n'` characters written are translated to the system default line separator, `os.linesep`. If `newline` is `' '`, no translation takes place. If `newline` is any of the other legal values, any `'\n'` characters written are translated to the given string.

If `closefd` is `False` and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given `closefd` has no effect and must be `True` (the default).

The type of file object returned by the `open()` function depends on the mode. When `open()` is used to open a file in a text mode (`'w'`, `'r'`, `'wt'`, `'rt'`, etc.), it returns a subclass of `TextIOBase` (specifically `TextIOWrapper`). When used to open a file in a binary mode with buffering, the returned class is a subclass of `BufferedIOBase`. The exact class varies: in read binary mode, it returns a `BufferedReader`; in write binary and append binary modes, it returns a `BufferedWriter`, and in read/write mode, it returns a `BufferedRandom`. When buffering is disabled, the raw stream, a subclass of `RawIOBase`, `FileIO`, is returned.

It is also possible to use an *unicode* or *bytes* string as a file for both reading and writing. For *unicode* strings `StringIO` can be used like a file opened in text mode, and for *bytes* a `BytesIO` can be used like a file opened in a binary mode.

exception `io.BlockingIOError`

Error raised when blocking would occur on a non-blocking stream. It inherits `IOError`.

In addition to those of `IOError`, `BlockingIOError` has one attribute:

`characters_written`

An integer containing the number of characters written to the stream before it blocked.

exception `io.UnsupportedOperation`

An exception inheriting `IOError` and `ValueError` that is raised when an unsupported operation is called on a stream.

15.2.2 I/O Base Classes

class `io.IOBase`

The abstract base class for all I/O classes, acting on streams of bytes. There is no public constructor.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though `IOBase` does not declare `read()`, `readinto()`, or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise an `IOError` when operations they do not support are called.

The basic type used for binary data read from or written to a file is `bytes` (also known as *str*). Method arguments may also be *bytearray* or *memoryview* of arrays of bytes. In some cases, such as `readinto()`, a writable object such as *bytearray* is required. Text I/O classes work with *unicode* data.

Changed in version 2.7: Implementations should support *memoryview* arguments.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise *IOError* in this case.

IOBase (and its subclasses) support the iterator protocol, meaning that an *IOBase* object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding *bytes*), or a text stream (yielding *unicode* strings). See *readline()* below.

IOBase is also a context manager and therefore supports the *with* statement. In this example, *file* is closed after the *with* statement's suite is finished—even if an exception occurs:

```
with io.open('spam.txt', 'w') as file:
    file.write(u'Spam and eggs!')
```

IOBase provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a *ValueError*.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

closed

True if the stream is closed.

fileno()

Return the underlying file descriptor (an integer) of the stream if it exists. An *IOError* is raised if the *IO* object does not use a file descriptor.

flush()

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()

Return *True* if the stream is interactive (i.e., connected to a terminal/tty device).

readable()

Return *True* if the stream can be read from. If *False*, *read()* will raise *IOError*.

readline(*limit=-1*)

Read and return one line from the stream. If *limit* is specified, at most *limit* bytes will be read.

The line terminator is always *b'\n'* for binary files; for text files, the *newline* argument to *open()* can be used to select the line terminator(s) recognized.

readlines(*hint=-1*)

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

Note that it's already possible to iterate on file objects using *for line in file: ...* without calling *file.readlines()*.

seek(*offset*[, *whence*])

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is *SEEK_SET*. Values for *whence* are:

- *SEEK_SET* or 0 – start of the stream (the default); *offset* should be zero or positive
- *SEEK_CUR* or 1 – current stream position; *offset* may be negative
- *SEEK_END* or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

New in version 2.7: The *SEEK_** constants

seekable()

Return True if the stream supports random access. If False, `seek()`, `tell()` and `truncate()` will raise `IOError`.

tell()

Return the current stream position.

truncate(size=None)

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled, on Windows they're undetermined). The new file size is returned.

writable()

Return True if the stream supports writing. If False, `write()` and `truncate()` will raise `IOError`.

writelines(lines)

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

__del__()

Prepare for object destruction. `IOBase` provides a default implementation of this method that calls the instance's `close()` method.

class io.RawIOBase

Base class for raw binary I/O. It inherits `IOBase`. There is no public constructor.

Raw binary I/O typically provides low-level access to an underlying OS device or API, and does not try to encapsulate it in high-level primitives (this is left to Buffered I/O and Text I/O, described later in this page).

In addition to the attributes and methods from `IOBase`, `RawIOBase` provides the following methods:

read(n=-1)

Read up to *n* bytes from the object and return them. As a convenience, if *n* is unspecified or -1, `readall()` is called. Otherwise, only one system call is ever made. Fewer than *n* bytes may be returned if the operating system call returns fewer than *n* bytes.

If 0 bytes are returned, and *n* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

readall()

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(b)

Read up to `len(b)` bytes into *b*, and return the number of bytes read. The object *b* should be a pre-allocated, writable array of bytes, either `bytearray` or `memoryview`. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(b)

Write *b* to the underlying raw stream, and return the number of bytes written. The object *b* should be an array of bytes, either `bytes`, `bytearray`, or `memoryview`. The return value can be less than `len(b)`, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

class io.BufferedIOBase

Base class for binary streams that support some kind of buffering. It inherits `IOBase`. There is no public constructor.

The main difference with `RawIOBase` is that methods `read()`, `readinto()` and `write()` will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise `BlockingIOError` if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their `RawIOBase` counterparts, they will never return `None`.

Besides, the `read()` method does not have a default implementation that defers to `readinto()`.

A typical `BufferedIOBase` implementation should not inherit from a `RawIOBase` implementation, but wrap one, like `BufferedWriter` and `BufferedReader` do.

`BufferedIOBase` provides or overrides these methods and attribute in addition to those from `IOBase`:

raw

The underlying raw stream (a `RawIOBase` instance) that `BufferedIOBase` deals with. This is not part of the `BufferedIOBase` API and may not exist on some implementations.

detach()

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like `BytesIO`, do not have the concept of a single raw stream to return from this method. They raise `UnsupportedOperation`.

New in version 2.7.

read(n=-1)

Read and return up to *n* bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty bytes object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

read1(n=-1)

Read and return up to *n* bytes, with at most one call to the underlying raw stream's `read()` method. This can be useful if you are implementing your own buffering on top of a `BufferedIOBase` object.

readinto(b)

Read up to `len(b)` bytes into *b*, and return the number of bytes read. The object *b* should be a pre-allocated, writable array of bytes, either `bytearray` or `memoryview`.

Like `read()`, multiple reads may be issued to the underlying raw stream, unless the latter is 'interactive'.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

write(b)

Write *b*, and return the number of bytes written (always equal to `len(b)`, since if the write fails an `IOError` will be raised). The object *b* should be an array of bytes, either `bytes`, `bytearray`, or `memoryview`. Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a `BlockingIOError` is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

15.2.3 Raw File I/O

class `io.FileIO` (*name*, *mode*='r', *closefd*=True)

FileIO represents an OS-level file containing bytes data. It implements the *RawIOBase* interface (and therefore the *IOBase* interface, too).

The *name* can be one of two things:

- a string representing the path to the file which will be opened;
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access.

The *mode* can be 'r', 'w' or 'a' for reading (default), writing, or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. Add a '+' to the mode to allow simultaneous reading and writing.

The `read()` (when called with a positive argument), `readinto()` and `write()` methods on this class will only make one system call.

In addition to the attributes and methods from *IOBase* and *RawIOBase*, *FileIO* provides the following data attributes and methods:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

15.2.4 Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class `io.BytesIO` ([*initial_bytes*])

A stream implementation using an in-memory bytes buffer. It inherits *BufferedIOBase*.

The optional argument *initial_bytes* is a `bytes` object that contains initial data.

BytesIO provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

getvalue()

Return bytes containing the entire contents of the buffer.

read1()

In *BytesIO*, this is the same as `read()`.

class `io.BufferedReader` (*raw*, *buffer_size*=DEFAULT_BUFFER_SIZE)

A buffer providing higher-level access to a readable, sequential *RawIOBase* object. It inherits *BufferedIOBase*. When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, *DEFAULT_BUFFER_SIZE* is used.

BufferedReader provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

peek ([*n*])

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

read (*[n]*)

Read and return *n* bytes, or if *n* is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1 (*n*)

Read and return up to *n* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

class `io.BufferedWriter` (*raw, buffer_size=DEFAULT_BUFFER_SIZE*)

A buffer providing higher-level access to a writeable, sequential `RawIOBase` object. It inherits `BufferedIOBase`. When writing to this object, data is normally held into an internal buffer. The buffer will be written out to the underlying `RawIOBase` object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to `DEFAULT_BUFFER_SIZE`.

A third argument, *max_buffer_size*, is supported, but unused and deprecated.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

flush ()

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

write (*b*)

Write *b*, and return the number of bytes written. The object *b* should be an array of bytes, either `bytes`, `bytearray`, or `memoryview`. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

class `io.BufferedReader` (*raw, buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered interface to random access streams. It inherits `BufferedReader` and `BufferedWriter`, and further supports `seek()` and `tell()` functionality.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

A third argument, *max_buffer_size*, is supported, but unused and deprecated.

`BufferedReader` is capable of anything `BufferedReader` or `BufferedWriter` can do.

class `io.BufferedRWPair` (*reader, writer, buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered I/O object combining two unidirectional `RawIOBase` objects – one readable, the other writeable – into a single bidirectional endpoint. It inherits `BufferedIOBase`.

reader and *writer* are `RawIOBase` objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

A fourth argument, *max_buffer_size*, is supported, but unused and deprecated.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

Warning: *BufferedReader* does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use *BufferedReader* instead.

15.2.5 Text I/O

class `io.TextIOBase`

Base class for text streams. This class provides a unicode character and line based interface to stream I/O. There is no `readinto()` method because Python's *unicode* strings are immutable. It inherits *IOBase*. There is no public constructor.

TextIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or *None*, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a *BufferedReader* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist on some implementations.

detach()

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

New in version 2.7.

read(*n=-1*)

Read and return at most *n* characters from the stream as a single *unicode*. If *n* is negative or *None*, reads until EOF.

readline(*limit=-1*)

Read until newline or EOF and return a single *unicode*. If the stream is already at EOF, an empty string is returned.

If *limit* is specified, at most *limit* characters will be read.

seek(*offset*[, *whence*])

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is *SEEK_SET*.

- *SEEK_SET* or 0: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- *SEEK_CUR* or 1: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- *SEEK_END* or 2: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

New in version 2.7: The *SEEK_** constants.

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(s)

Write the *unicode* string *s* to the stream and return the number of characters written.

class io.TextIOWrapper (*buffer, encoding=None, errors=None, newline=None, line_buffering=False*)

A buffered text stream over a *BufferedIOBase* binary stream. It inherits *TextIOBase*.

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getpreferredencoding()*.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass 'strict' to raise a *ValueError* exception if there is an encoding error (the default of *None* has the same effect), or pass 'ignore' to ignore errors. (Note that ignoring encoding errors can lead to data loss.) 'replace' causes a replacement marker (such as '?') to be inserted where there is malformed data. When writing, 'xmlcharrefreplace' (replace with the appropriate XML character reference) or 'backslashreplace' (replace with backslashed escape sequences) can be used. Any other error handling name that has been registered with *codecs.register_error()* is also valid.

newline controls how line endings are handled. It can be *None*, ' ', '\n', '\r', and '\r\n'. It works as follows:

- On input, if *newline* is *None*, *universal newlines* mode is enabled. Lines in the input can end in '\n', '\r', or '\r\n', and these are translated into '\n' before being returned to the caller. If it is ' ', universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- On output, if *newline* is *None*, any '\n' characters written are translated to the system default line separator, *os.linesep*. If *newline* is ' ', no translation takes place. If *newline* is any of the other legal values, any '\n' characters written are translated to the given string.

If *line_buffering* is *True*, *flush()* is implied when a call to write contains a newline character or a carriage return.

TextIOWrapper provides one attribute in addition to those of *TextIOBase* and its parents:

line_buffering

Whether line buffering is enabled.

class io.StringIO (*initial_value=u'', newline=u'\n'*)

An in-memory stream for unicode text. It inherits *TextIOWrapper*.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer.

The *newline* argument works like that of *TextIOWrapper*. The default is to consider only \n characters as ends of lines and to do no newline translation. If *newline* is set to *None*, newlines are written as \n on all platforms, but universal newline decoding is still performed when reading.

StringIO provides this method in addition to those from *TextIOWrapper* and its parents:

getvalue()

Return a *unicode* containing the entire contents of the buffer at any time before the *StringIO* object's *close()* method is called. Newlines are decoded as if by *read()*, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write(u'First line.\n')
output.write(u'Second line.\n')

# Retrieve file contents -- this will be
# u'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class `io.IncrementalNewlineDecoder`

A helper codec that decodes newlines for *universal newlines* mode. It inherits *codecs.IncrementalDecoder*.

15.2.6 Advanced topics

Here we will discuss several advanced topics pertaining to the concrete I/O implementations described above.

Performance

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O is designed to hide any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain will vary very much depending on the OS and the kind of I/O which is performed (for example, on some contemporary OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O). The bottom line, however, is that buffered I/O will offer you predictable performance regardless of the platform and the backing device. Therefore, it is most always preferable to use buffered I/O rather than unbuffered I/O.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it implies conversions from unicode to binary data using a character codec. This can become noticeable if you handle huge amounts of text data (for example very large log files). Also, `TextIOWrapper.tell()` and `TextIOWrapper.seek()` are both quite slow due to the reconstruction algorithm used.

StringIO, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

Multi-threading

FileIO objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they are wrapping are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) are not reentrant. While reentrant calls will not happen in normal situations, they can arise if you are doing I/O in a `signal` handler. If it is attempted to enter a buffered object again while already being accessed *from the same thread*, then a `RuntimeError` is raised.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in function `print()` as well.

15.3 `time` — Time access and conversions

This module provides various time-related functions. For related functionality, see also the `datetime` and `calendar` modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts. On January 1st of that year, at 0 hours, the “time since the epoch” is zero. For Unix, the epoch is 1970. To find out what the epoch is, look at `gmtime(0)`.
- The functions in this module do not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library; for Unix, it is typically in 2038.
- **Year 2000 (Y2K) issues:** Python depends on the platform’s C library, which generally doesn’t have year 2000 issues, since all dates and times are represented internally as seconds since the epoch. Functions accepting a `struct_time` (see below) generally require a 4-digit year. For backward compatibility, 2-digit years are supported if the module variable `accept2dyear` is a non-zero integer; this variable is initialized to 1 unless the environment variable `PYTHONY2K` is set to a non-empty string, in which case it is initialized to 0. Thus, you can set `PYTHONY2K` to a non-empty string in the environment to require 4-digit years for all year input. When 2-digit years are accepted, they are converted according to the POSIX or X/Open standard: values 69-99 are mapped to 1969-1999, and values 0-68 are mapped to 2000-2068. Values 100-1899 are always illegal.
- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock “ticks” only 50 or 100 times a second.
- On the other hand, the precision of `time()` and `sleep()` is better than their Unix equivalents: times are expressed as floating point numbers, `time()` returns the most accurate time available (using `gettimeofday()` where available), and `sleep()` will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by `gmtime()`, `localtime()`, and `strptime()`, and accepted by `asctime()`, `mktime()` and `strftime()`, may be considered as a sequence of 9 integers. The return values of `gmtime()`, `localtime()`, and `strptime()` also offer attribute names for individual fields.

See `struct_time` for a description of these objects.

Changed in version 2.2: The time value sequence was changed from a tuple to a `struct_time`, with the addition of attribute names for the fields.

- Use the following functions to convert between time representations:

| From | To | Use |
|--|--|--------------------------------|
| seconds since the epoch | <code>struct_time</code> in UTC | <code>gmtime()</code> |
| seconds since the epoch | <code>struct_time</code> in local time | <code>localtime()</code> |
| <code>struct_time</code> in UTC | seconds since the epoch | <code>calendar.timegm()</code> |
| <code>struct_time</code> in local time | seconds since the epoch | <code>mktime()</code> |

The module defines the following functions and data items:

`time.accept2dyear`

Boolean value indicating whether two-digit year values will be accepted. This is true by default, but will be set to false if the environment variable `PYTHON2K` has been set to a non-empty string. It may also be modified at run time.

`time.altzone`

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero.

`time.asctime([t])`

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a 24-character string of the following form: 'Sun Jun 20 23:21:05 1993'. If `t` is not provided, the current time as returned by `localtime()` is used. Locale information is not used by `asctime()`.

Note: Unlike the C function of the same name, there is no trailing newline.

Changed in version 2.1: Allowed `t` to be omitted.

`time.clock()`

On Unix, return the current processor time as a floating point number expressed in seconds. The precision, and in fact the very definition of the meaning of “processor time”, depends on that of the C function of the same name, but in any case, this is the function to use for benchmarking Python or timing algorithms.

On Windows, this function returns wall-clock seconds elapsed since the first call to this function, as a floating point number, based on the Win32 function `QueryPerformanceCounter()`. The resolution is typically better than one microsecond.

`time.ctime([secs])`

Convert a time expressed in seconds since the epoch to a string representing local time. If `secs` is not provided or `None`, the current time as returned by `time()` is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by `ctime()`.

Changed in version 2.1: Allowed `secs` to be omitted.

Changed in version 2.4: If `secs` is `None`, the current time is used.

`time.daylight`

Nonzero if a DST timezone is defined.

`time.gmtime([secs])`

Convert a time expressed in seconds since the epoch to a `struct_time` in UTC in which the dst flag is always zero. If `secs` is not provided or `None`, the current time as returned by `time()` is used. Fractions of a second are ignored. See above for a description of the `struct_time` object. See `calendar.timegm()` for the inverse of this function.

Changed in version 2.1: Allowed *secs* to be omitted.

Changed in version 2.4: If *secs* is *None*, the current time is used.

`time.localtime([secs])`

Like *gmtime()* but converts to local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. The dst flag is set to 1 when DST applies to the given time.

Changed in version 2.1: Allowed *secs* to be omitted.

Changed in version 2.4: If *secs* is *None*, the current time is used.

`time.mktime(t)`

This is the inverse function of *localtime()*. Its argument is the *struct_time* or full 9-tuple (since the dst flag is needed; use -1 as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

`time.sleep(secs)`

Suspend execution of the current thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time. The actual suspension time may be less than that requested because any caught signal will terminate the *sleep()* following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system.

`time.strftime(format[, t])`

Convert a tuple or *struct_time* representing a time as returned by *gmtime()* or *localtime()* to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by *localtime()* is used. *format* must be a string. *ValueError* is raised if any field in *t* is outside of the allowed range. *strftime()* returns a locale dependent byte string; the result may be converted to unicode by doing `strftime(<myformat>).decode(locale.getlocale()[1])`.

Changed in version 2.1: Allowed *t* to be omitted.

Changed in version 2.4: *ValueError* raised if a field in *t* is out of range.

Changed in version 2.5: 0 is now a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the *strftime()* result:

| Di- rec- tive | Meaning | Notes |
|---------------------|--|-------|
| %a | Locale's abbreviated weekday name. | |
| %A | Locale's full weekday name. | |
| %b | Locale's abbreviated month name. | |
| %B | Locale's full month name. | |
| %c | Locale's appropriate date and time representation. | |
| %d | Day of the month as a decimal number [01,31]. | |
| %H | Hour (24-hour clock) as a decimal number [00,23]. | |
| %I | Hour (12-hour clock) as a decimal number [01,12]. | |
| %j | Day of the year as a decimal number [001,366]. | |
| %m | Month as a decimal number [01,12]. | |
| %M | Minute as a decimal number [00,59]. | |
| %p | Locale's equivalent of either AM or PM. | (1) |
| %S | Second as a decimal number [00,61]. | (2) |
| %U | Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. | (3) |
| %w | Weekday as a decimal number [0(Sunday),6]. | |
| %W | Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0. | (3) |
| %x | Locale's appropriate date representation. | |
| %X | Locale's appropriate time representation. | |
| %y | Year without century as a decimal number [00,99]. | |
| %Y | Year with century as a decimal number. | |
| %Z | Time zone name (no characters if no time zone exists). | |
| %% | A literal '%' character. | |

Notes:

- (1) When used with the `strptime()` function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (2) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (3) When used with the `strptime()` function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the [RFC 2822](#) Internet email standard.¹

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial '%' of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

¹ The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 [RFC 822](#) standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, [RFC 822](#) became obsolete and the 4-digit year has been first recommended by [RFC 1123](#) and then mandated by [RFC 2822](#).

`time.strptime(string[, format])`

Parse a string representing a time according to a format. The return value is a *struct_time* as returned by *gmtime()* or *localtime()*.

The *format* parameter uses the same directives as those used by *strftime()*; it defaults to "%a %b %d %H:%M:%S %Y" which matches the formatting returned by *ctime()*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *ValueError* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are (1900, 1, 1, 0, 0, 0, 0, 1, -1).

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")    # doctest: +NORMALIZE_WHITESPACE
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                 tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the %Z directive is based on the values contained in *tzname* and whether *daylight* is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because *strftime()* is implemented per platform it can sometimes offer more directives than those listed. But *strptime()* is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

class `time.struct_time`

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface: values can be accessed by index and by attribute name. The following values are present:

| Index | Attribute | Values |
|-------|-----------------|---|
| 0 | <i>tm_year</i> | (for example, 1993) |
| 1 | <i>tm_mon</i> | range [1, 12] |
| 2 | <i>tm_mday</i> | range [1, 31] |
| 3 | <i>tm_hour</i> | range [0, 23] |
| 4 | <i>tm_min</i> | range [0, 59] |
| 5 | <i>tm_sec</i> | range [0, 61]; see (2) in <i>strftime()</i> description |
| 6 | <i>tm_wday</i> | range [0, 6], Monday is 0 |
| 7 | <i>tm_yday</i> | range [1, 366] |
| 8 | <i>tm_isdst</i> | 0, 1 or -1; see below |

New in version 2.2.

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11]. A year value will be handled as described under *Year 2000 (Y2K) issues* above.

In calls to *mktime()*, *tm_isdst* may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct_time*, or having elements of the wrong type, a *TypeError* is raised.

`time.time()`

Return the time in seconds since the epoch as a floating point number. Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

time.timezone

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK).

time.tzname

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used.

time.tzset()

Reset the time conversion rules used by the library routines. The environment variable TZ specifies how this is done. It will also set the variables `tzname` (from the TZ environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

New in version 2.3.

Availability: Unix.

Note: Although in many cases, changing the TZ environment variable may affect the output of functions like `localtime()` without calling `tzset()`, this behavior should not be relied on.

The TZ environment variable should contain no whitespace.

The standard format of the TZ environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are:

std and dst Three or more alphanumerics giving the timezone abbreviations. These will be propagated into `time.tzname`

offset The offset has the form: $\pm hh[:mm[:ss]]$. This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows `dst`, summer time is assumed to be one hour ahead of standard time.

start[/time], end[/time] Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

Jn The Julian day n ($1 \leq n \leq 365$). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

n The zero-based Julian day ($0 \leq n \leq 365$). Leap days are counted, and it is possible to refer to February 29.

Mm.n.d The d 'th day ($0 \leq d \leq 6$) or week n of month m of the year ($1 \leq n \leq 5$, $1 \leq m \leq 12$, where week 5 means "the last d day in month m " which may occur in either the fourth or the fifth week). Week 1 is the first week in which the d 'th day occurs. Day zero is Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if time is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*tzfile(5)*) database to specify the timezone rules. To do this, set the TZ environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, 'US/Eastern', 'Australia/Melbourne', 'Egypt' or 'Europe/Amsterdam'.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

15.4 argparse — Parser for command-line options, arguments and sub-commands

New in version 2.7.

Source code: [Lib/argparse.py](#)

Tutorial

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the [argparse tutorial](#).

The *argparse* module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and *argparse* will figure out how to parse those out of *sys.argv*. The *argparse* module also automatically generates help and usage messages and issues errors when users give the program invalid arguments.

15.4.1 Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
                    help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
                    help='sum the integers (default: find the max)')
```

(continues on next page)

(continued from previous page)

```
args = parser.parse_args()
print args.accumulate(args.integers)
```

Assuming the Python code above is saved into a file called `prog.py`, it can be run at the command line and provides useful help messages:

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
  N              an integer for the accumulator

optional arguments:
  -h, --help    show this help message and exit
  --sum         sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, it will issue an error:

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

Creating a parser

The first step in using the `argparse` is creating an `ArgumentParser` object:

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

The `ArgumentParser` object will hold all the information necessary to parse the command line into Python data types.

Adding arguments

Filling an `ArgumentParser` with information about program arguments is done by making calls to the `add_argument()` method. Generally, these calls tell the `ArgumentParser` how to take the strings on the command line and turn them into objects. This information is stored and used when `parse_args()` is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                     const=sum, default=max,
...                     help='sum the integers (default: find the max)')
```

Later, calling `parse_args()` will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more ints, and the `accumulate` attribute will be either the `sum()` function, if `--sum` was specified at the command line, or the `max()` function if it was not.

Parsing arguments

`ArgumentParser` parses arguments through the `parse_args()` method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple `Namespace` object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, `parse_args()` will typically be called with no arguments, and the `ArgumentParser` will automatically determine the command-line arguments from `sys.argv`.

15.4.2 ArgumentParser objects

class `argparse.ArgumentParser` (*prog=None, usage=None, description=None, epilog=None, parents=[], formatter_class=argparse.HelpFormatter, prefix_chars='-', fromfile_prefix_chars=None, argument_default=None, conflict_handler='error', add_help=True*)

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- *prog* - The name of the program (default: `sys.argv[0]`)
- *usage* - The string describing the program usage (default: generated from arguments added to parser)
- *description* - Text to display before the argument help (default: none)
- *epilog* - Text to display after the argument help (default: none)
- *parents* - A list of `ArgumentParser` objects whose arguments should also be included
- *formatter_class* - A class for customizing the help output
- *prefix_chars* - The set of characters that prefix optional arguments (default: '-')
- *fromfile_prefix_chars* - The set of characters that prefix files from which additional arguments should be read (default: None)
- *argument_default* - The global default value for arguments (default: None)
- *conflict_handler* - The strategy for resolving conflicting optionals (usually unnecessary)
- *add_help* - Add a `-h/--help` option to the parser (default: True)

The following sections describe how each of these are used.

prog

By default, `ArgumentParser` objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to [ArgumentParser](#):

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

optional arguments:
  -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo of the myprogram program
```

usage

By default, [ArgumentParser](#) calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
  bar                bar help
```

(continues on next page)

(continued from previous page)

```
optional arguments:
  -h, --help    show this help message and exit
  --foo [FOO]  foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='% (prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
  bar                bar help

optional arguments:
  -h, --help    show this help message and exit
  --foo [FOO]  foo help
```

The `% (prog)s` format specifier is available to fill in the program name in your usage messages.

description

Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
  -h, --help    show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the `formatter_class` argument.

epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
```

(continues on next page)

(continued from previous page)

```
-h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the *description* argument, the *epilog*= text is by default line-wrapped, but this behavior can be adjusted with the *formatter_class* argument to *ArgumentParser*.

parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to *parents*= argument to *ArgumentParser* can be used. The *parents*= argument takes a list of *ArgumentParser* objects, collects all the positional and optional actions from them, and adds these actions to the *ArgumentParser* object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify *add_help=False*. Otherwise, the *ArgumentParser* will see two *-h/--help* options (one in the parent and one in the child) and raise an error.

Note: You must fully initialize the parsers before passing them via *parents*=. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are three such classes:

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
```

The first two allow more control over how textual descriptions are displayed, while the last automatically adds information about argument default values.

By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
```

(continues on next page)

(continued from previous page)

```

...     epilog=''
...         likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines'''
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
  -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines

```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped:

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         -----
...             I have indented it
...             exactly the way
...             I want it
...         '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
-----
    I have indented it
    exactly the way
    I want it

optional arguments:
  -h, --help  show this help message and exit

```

RawTextHelpFormatter maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

The other formatter class available, *ArgumentDefaultsHelpFormatter*, will add information about the default value of each of the arguments:

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar [bar ...]]

positional arguments:
  bar                BAR! (default: [1, 2, 3])

```

(continues on next page)

(continued from previous page)

```
optional arguments:
-h, --help  show this help message and exit
--foo FOO   FOO! (default: 42)
```

prefix_chars

Most command-line options will use `-` as the prefix, e.g. `-f`/`--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the `ArgumentParser` constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f`/`--foo` options to be disallowed.

fromfile_prefix_chars

Sometimes, for example when dealing with a particularly long argument lists, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the `ArgumentParser` constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also `convert_arg_line_to_args()`) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

argument_default

Generally, argument defaults are specified either by passing a default to `add_argument()` or by calling the `set_defaults()` methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to `ArgumentParser`. For example, to globally suppress attribute creation on `parse_args()` calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
```

(continues on next page)

(continued from previous page)

```
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

conflict_handler

ArgumentParser objects do not allow two actions with the same option string. By default, *ArgumentParser* objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value 'resolve' can be supplied to the `conflict_handler=` argument of *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  -f FOO      old foo help
  --foo FOO   new foo help
```

Note that *ArgumentParser* objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

add_help

By default, *ArgumentParser* objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the *ArgumentParser* help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

optional arguments:
  --foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

optional arguments:
  +h, ++help  show this help message and exit
```

15.4.3 The `add_argument()` method

`ArgumentParser.add_argument` (*name or flags...* [, *action*] [, *nargs*] [, *const*] [, *default*] [, *type*] [, *choices*] [, *required*] [, *help*] [, *metavar*] [, *dest*])

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- *name or flags* - Either a name or a list of option strings, e.g. `foo` or `-f`, `--foo`.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A container of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by `parse_args()`.

The following sections describe how each of these are used.

name or flags

The `add_argument()` method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to `add_argument()` must therefore be either a series of flags, or a simple argument name. For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: too few arguments
```

action

`ArgumentParser` objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by `parse_args()`. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args('--foo 1'.split())
Namespace(foo='1')
```

- `'store_const'` - This stores the value specified by the `const` keyword argument. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const', const=42)
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` using for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(bar=False, baz=True, foo=True)
```

- `'append'` - This stores a list, and appends each argument value to the list. This is useful to allow an option to be specified multiple times. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- 'append_const' - This stores a list, and appends the value specified by the *const* keyword argument to the list. (Note that the *const* keyword argument defaults to None.) The 'append_const' action is typically useful when multiple arguments need to store constants to the same list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<type 'str'>, <type 'int'>])
```

- 'count' - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count')
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

- 'help' - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See *ArgumentParser* for details of how the output is created.
- 'version' - This expects a *version=* keyword argument in the *add_argument()* call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='% (prog)s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The recommended way to do this is to extend *Action*, overriding the `__call__` method and optionally the `__init__` method.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super(FooAction, self).__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print '%r %r %r' % (namespace, values, option_string)
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

For more details, see [Action](#).

nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])
```

Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from [default](#) will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from [const](#) will be produced. Some examples to illustrate this:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')
```

One of the more common uses of `nargs='?'` is to allow optional input and output files:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<open file 'input.txt', mode 'r' at 0x...>,
          outfile=<open file 'output.txt', mode 'w' at 0x...>)
>>> parser.parse_args([])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>,
          outfile=<open file '<stdout>', mode 'w' at 0x...>)
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
```

(continues on next page)

(continued from previous page)

```
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: too few arguments
```

- `argparse.REMAINDER`. All the remaining command-line arguments are gathered into a list. This is commonly useful for command line utilities that dispatch to other command line utilities:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo')
>>> parser.add_argument('command')
>>> parser.add_argument('args', nargs=argparse.REMAINDER)
>>> print parser.parse_args('--foo B cmd --arg1 XX ZZ'.split())
Namespace(args=['--arg1', 'XX', 'ZZ'], command='cmd', foo='B')
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the [action](#). Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced.

const

The `const` argument of `add_argument()` is used to hold constant values that are not read from the command line but are required for the various `ArgumentParser` actions. The two most common uses of it are:

- When `add_argument()` is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by `parse_args()`. See the [action](#) description for examples.
- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed instead. See the [nargs](#) description for examples.

With the `'store_const'` and `'append_const'` actions, the `const` keyword argument must be given. For other actions, it defaults to `None`.

default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
```

(continues on next page)

(continued from previous page)

```
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the default value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *Namespace* return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the default value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present.:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, *ArgumentParser* objects read command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, like a *float* or *int*. The *type* keyword argument of *add_argument()* allows any necessary type-checking and type conversions to be performed. Common built-in types and functions can be used directly as the value of the *type* argument:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.add_argument('bar', type=file)
>>> parser.parse_args('2 temp.txt'.split())
Namespace(bar=<open file 'temp.txt', mode 'r' at 0x...>, foo=2)
```

See the section on the *default* keyword argument for information on when the *type* argument is applied to default arguments.

To ease the use of various types of files, the *argparse* module provides the factory *FileType* which takes the *mode=* and *bufsize=* arguments of the file object. For example, *FileType('w')* can be used to create a writable file:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['out.txt'])
Namespace(bar=<open file 'out.txt', mode 'w' at 0x...>)
```

`type=` can take any callable that takes a single string argument and returns the converted value:

```
>>> def perfect_square(string):
...     value = int(string)
...     sqrt = math.sqrt(value)
...     if sqrt != int(sqrt):
...         msg = "%r is not a perfect square" % string
...         raise argparse.ArgumentTypeError(msg)
...     return value
...
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=perfect_square)
>>> parser.parse_args(['9'])
Namespace(foo=9)
>>> parser.parse_args(['7'])
usage: PROG [-h] foo
PROG: error: argument foo: '7' is not a perfect square
```

The *choices* keyword argument may be more convenient for type checkers that simply check against a range of values:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=int, choices=xrange(5, 10))
>>> parser.parse_args(['7'])
Namespace(foo=7)
>>> parser.parse_args(['11'])
usage: PROG [-h] {5,6,7,8,9}
PROG: error: argument foo: invalid choice: 11 (choose from 5, 6, 7, 8, 9)
```

See the *choices* section for more details.

choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the *choices* keyword argument to *add_argument()*. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any *type* conversions have been performed, so the type of the objects in the *choices* container should match the *type* specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
```

(continues on next page)

(continued from previous page)

```

Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)

```

Any object that supports the `in` operator can be passed as the *choices* value, so *dict* objects, *set* objects, custom containers, etc. are all supported.

required

In general, the *argparse* module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to *add_argument()*:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: argparse.py [-h] [--foo FOO]
argparse.py: error: option --foo is required

```

As the example shows, if an option is marked as required, *parse_args()* will report an error if that option is not present at the command line.

Note: Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

help

The *help* value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these *help* descriptions will be displayed with each argument:

```

>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
...                     help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
  bar                one of the bars to be frobbled

optional arguments:
  -h, --help        show this help message and exit
  --foo            foo the bars before frobbling

```

The *help* strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to *add_argument()*, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                      help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
  bar      the bar to frobble (default: 42)

optional arguments:
  -h, --help  show this help message and exit
```

`argparse` supports silencing the help entry for certain options, by setting the help value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

optional arguments:
  -h, --help  show this help message and exit
```

metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the “name” of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo FOO] bar

positional arguments:
  bar

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo YYY] XXX
```

(continues on next page)

(continued from previous page)

```
positional arguments:
  XXX

optional arguments:
  -h, --help  show this help message and exit
  --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the *dest* value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

optional arguments:
  -h, --help      show this help message and exit
  -x X X
  --foo bar baz
```

dest

Most `ArgumentParser` actions add some value as an attribute of the object returned by `parse_args()`. The name of this attribute is determined by the `dest` keyword argument of `add_argument()`. For positional argument actions, `dest` is normally supplied as the first argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. `ArgumentParser` generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to `add_argument()`.

```
class argparse.Action(option_strings, dest, nargs=None, const=None, default=None, type=None,
                      choices=None, required=False, help=None, metavar=None)
```

Action objects are used by an `ArgumentParser` to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to `ArgumentParser.add_argument()` except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes “`dest`”, “`option_strings`”, “`default`”, “`type`”, “`required`”, “`help`”, etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters:

- `parser` - The `ArgumentParser` object which contains this action.
- `namespace` - The `Namespace` object that will be returned by `parse_args()`. Most actions add an attribute to this object using `setattr()`.
- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the `type` keyword argument to `add_argument()`.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

15.4.4 The `parse_args()` method

`ArgumentParser.parse_args(args=None, namespace=None)`

Convert argument strings to objects and assign them as attributes of the `namespace`. Return the populated `namespace`.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- `args` - List of strings to parse. The default is taken from `sys.argv`.
- `namespace` - An object to take the attributes. The default is a new empty `Namespace` object.

Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing –

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

Argument abbreviations (prefix matching)

The `parse_args()` method allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args(['-bac MMM'].split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args(['-bad WOOD'].split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args(['-ba BA'].split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options.

Beyond `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=xrange(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

The Namespace object

`class` `argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an *object* subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an *ArgumentParser* assign attributes to an already existing object, rather than a new *Namespace* object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C(object):
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

15.4.5 Other utilities

Sub-commands

`ArgumentParser.add_subparsers` (*[title][, description][, prog][, parser_class][, action][, option_string][, dest][, help][, metavar]*)

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. *ArgumentParser* supports the creation of such sub-commands with

the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any `ArgumentParser` constructor arguments, and returns an `ArgumentParser` object that can be modified as usual.

Description of parameters:

- `title` - title for the sub-parser group in help output; by default “subcommands” if description is provided, otherwise uses title for positional arguments
- `description` - description for the sub-parser group in help output, by default `None`
- `prog` - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- `parser_class` - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. `ArgumentParser`)
- `action` - the basic type of action to be taken when this argument is encountered at the command line
- `dest` - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- `help` - help for sub-parser group in help output, by default `None`
- `metavar` - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form `{cmd1, cmd2, ..}`

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...
```

(continues on next page)

(continued from previous page)

```
positional arguments:
  {a,b}    sub-command help
  a        a help
  b        b help

optional arguments:
  -h, --help  show this help message and exit
  --foo      foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar      bar help

optional arguments:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
  -h, --help      show this help message and exit
  --baz {X,Y,Z}  baz help
```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                   description='valid subcommands',
...                                   help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...

optional arguments:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}  additional help
```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print args.x * args.y
...
>>> def bar(args):
...     print '(%s)' % args.z
...
...
>>>
```

(continues on next page)

(continued from previous page)

```

>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))

```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work:

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')

```

FileType objects

class `argparse.FileType` (*mode='r', bufsize=None*)

The `FileType` factory creates objects that can be passed to the `type` argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes and buffer sizes:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--output', type=argparse.FileType('wb', 0))
>>> parser.parse_args(['--output', 'out'])
Namespace(output=<open file 'out', mode 'wb' at 0x...>)

```

`FileType` objects understand the pseudo-argument `'-'` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>)
```

Argument groups

`ArgumentParser.add_argument_group(title=None, description=None)`

By default, `ArgumentParser` groups command-line arguments into “positional arguments” and “optional arguments” when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar      bar help
  --foo FOO  foo help
```

The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo      foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual “positional arguments” and “optional arguments” sections.

Mutual exclusion

`ArgumentParser.add_mutually_exclusive_group(required=False)`

Create a mutually exclusive group. `argparse` will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The `add_mutually_exclusive_group()` method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of `add_argument_group()`.

Parser defaults

`ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

`ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
```

(continues on next page)

(continued from previous page)

```
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

Warning: *Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the `fromfile_prefix_chars` keyword argument to the `ArgumentParser` constructor) are read one argument per line. `convert_arg_line_to_args()` can be overridden for fancier reading.

This method takes a single argument *arg_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument:

```
def convert_arg_line_to_args(self, arg_line):  
    return arg_line.split()
```

Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that.

`ArgumentParser.error(message)`

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

15.4.6 Upgrading optparse code

Originally, the *argparse* module had attempted to maintain compatibility with *optparse*. However, *optparse* was difficult to extend transparently, particularly with the changes required to support the new *nargs=* specifiers and better usage messages. When most everything in *optparse* had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The *argparse* module improves on the standard library *optparse* module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like + and /.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom type and action.

A partial upgrade path from *optparse* to *argparse*:

- Replace all `optparse.OptionParser.add_option()` calls with `ArgumentParser.add_argument()` calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional `ArgumentParser.add_argument()` calls for the positional arguments. Keep in mind that what was previously called *options*, now in the *argparse* context is called *args*.
- Replace `optparse.OptionParser.disable_interspersed_args()` by setting *nargs* of a positional argument to *argparse.REMAINDER*, or use `parse_known_args()` to collect unparsed argument strings in a separate list.
- Replace callback actions and the `callback_*` keyword arguments with *type* or *action* arguments.
- Replace string names for *type* keyword arguments with the corresponding type objects (e.g. `int`, `float`, `complex`, etc).
- Replace `optparse.Values` with *Namespace* and `optparse.OptionError` and `optparse.OptionValueError` with *ArgumentError*.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.

- Replace the `OptionParser` constructor version argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

15.5 `optparse` — Parser for command line options

New in version 2.3.

Deprecated since version 2.7: The `optparse` module is deprecated and will not be developed further; development will continue with the `argparse` module.

Source code: [Lib/optparse.py](#)

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the old `getopt` module. `optparse` uses a more declarative style of command-line parsing: you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose", default=True,
                  help="don't print status messages to stdout")

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the “usual thing” on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, `optparse` sets attributes of the options object returned by `parse_args()` based on user-supplied command-line values. When `parse_args()` returns from parsing this command line, `options.filename` will be `"outfile"` and `options.verbose` will be `False`. `optparse` supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of

```
<yourscript> -h
<yourscript> --help
```

and `optparse` will print out a brief summary of your script's options:

```
Usage: <yourscript> [options]
```

Options:

```
-h, --help            show this help message and exit
-f FILE, --file=FILE  write report to FILE
-q, --quiet           don't print status messages to stdout
```

where the value of *yourscript* is determined at runtime (normally from `sys.argv[0]`).

15.5.1 Background

optparse was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section to acquaint yourself with them.

Terminology

argument a string entered on the command-line, and passed by the shell to `exec1()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term “word”.

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read “argument” as “an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]`”.

option an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen (“-”) followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by *optparse*.

Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren’t usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by *optparse*, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you’re exclusively targeting VMS, MS-DOS, and/or Windows.

option argument an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With *optparse*, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, `optparse` does not support this feature.

positional argument something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

required option an option that must be supplied on the command-line; note that the phrase "required option" is self-contradictory in English. `optparse` doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have "required options". Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the "Preferences" dialog of a GUI, or command-line

options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

15.5.2 Tutorial

While *optparse* is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any *optparse*-based program.

First, you need to import the `OptionParser` class; then, early in the main program, create an `OptionParser` instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell *optparse* what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, *optparse* encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct *optparse* to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` returns two values:

- `options`, an object containing values for all of your options—e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes: *action*, *type*, *dest* (destination), and *help*. Of these, *action* is the most fundamental.

Understanding option actions

Actions tell *optparse* what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into *optparse*; adding new actions is an advanced topic covered in section *Extending optparse*. Most actions tell *optparse* to store a value in some variable—for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, *optparse* defaults to `store`.

The store action

The most common option action is `store`, which tells *optparse* to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

For example:

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask *optparse* to parse it:

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When *optparse* sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is `"foo.txt"`.

Some other option types supported by *optparse* are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print options.num
```

will print `42`.

If you don't specify a type, *optparse* assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, *optparse* figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, *optparse* looks at the first short option string: the default destination for `-f` is `f`.

optparse also includes built-in long and complex types. Adding types is covered in section [Extending optparse](#).

Handling boolean (flag) options

Flag options—set a variable to true or false when a particular option is seen—are quite common. *optparse* supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values— see below.)

When `optparse` encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

Other actions

Some other actions supported by `optparse` are:

"store_const" store a constant value

"append" append this option's argument to a list

"count" increment a counter by one

"callback" call a specified function

These are covered in section *Reference Guide*, Reference Guide and section *Option Callbacks*.

Default values

All of the above examples involve setting some variable (the “destination”) when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. `optparse` lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the verbose/quiet example. If we want `optparse` to set `verbose` to `True` unless `-q` is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=True)
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=False)
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for `verbose` will be `True`: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the `set_defaults()` method of `OptionParser`, which you can call at any time before calling `parse_args()`:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

Generating help

`optparse`'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a *help* value for each option, and optionally a short usage message for your whole program. Here's an `OptionParser` populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose", default=True,
                  help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="be vewwy quiet (I'm hunting wabbits)")
parser.add_option("-f", "--filename",
                  metavar="FILE", help="write output to FILE")
parser.add_option("-m", "--mode",
                  default="intermediate",
                  help="interaction mode: novice, intermediate, "
                        "or expert [default: %default]")
```

If `optparse` encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output:

```
Usage: <yourscrip> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, `optparse` exits after printing the help text.)

There's a lot going on here to help `optparse` generate the best possible help message:

- the script defines its own usage message:

```
usage = "usage: %prog [options] arg1 arg2"
```

`optparse` expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don't supply a usage string, `optparse` uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping—`optparse` takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically-generated help message, e.g. for the “mode” option:

```
-m MODE, --mode=MODE
```

Here, “MODE” is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want—for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically-generated option description:

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description “write output to `FILE`”. This is a simple but effective way to make your help text a lot clearer and more useful for end users.

New in version 2.4: Options that have a default value can include `%default` in the help string—`optparse` will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup`:

```
class optparse.OptionGroup (parser, title, description=None)
    where
```

- `parser` is the `OptionParser` instance the group will be inserted in to
- `title` is the group title
- `description`, optional, is a long description of the group

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an `OptionGroup` to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk.  "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                    Group option.
```

A bit more complete example might involve using more than one group: still extending the previous example:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk.  "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every action done")
parser.add_option_group(group)
```

that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet            be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or expert
                        [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                    Group option.

Debug Options:
  -d, --debug          Print debug information
  -s, --sql            Print all SQL statements executed
  -e                  Print every action done
```

Another interesting method, in particular when working programmatically with option groups is:

`OptionParser.get_option_group(opt_str)`

Return the *OptionGroup* to which the short or long option string *opt_str* (e.g. `'-o'` or `'--option'`) belongs. If there's no such *OptionGroup*, return `None`.

Printing a version string

Similar to the brief usage string, *optparse* can also print a version string for your program. You have to supply the string as the `version` argument to `OptionParser`:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")
```

`%prog` is expanded just like it is in usage. Apart from that, `version` can contain anything you like. When you supply it, *optparse* automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your `version` string (by replacing `%prog`), prints it to stdout, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the version string:

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to *file* (default stdout). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

How `optparse` handles errors

There are two broad classes of errors that `optparse` has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. `optparse` can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
```

In either case, `optparse` handles the error the same way: it prints the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

`optparse`-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling `OptionParser.error()` from your application code.

If `optparse`'s default error-handling behaviour does not suit your needs, you'll need to subclass `OptionParser` and override its `exit()` and/or `error()` methods.

Putting it all together

Here's what `optparse`-based scripts usually look like:

```

from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
                      action="store_false", dest="verbose")
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print "reading %s..." % options.filename
    ...

if __name__ == "__main__":
    main()

```

15.5.3 Reference Guide

Creating the parser

The first step in using *optparse* is to create an *OptionParser* instance.

class *optparse.OptionParser* (...)

The *OptionParser* constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

usage (default: "%prog [options]") The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands %prog to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

option_list (default: []) A list of *Option* objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by *OptionParser* subclasses), but before any version or help options. Deprecated; use *add_option()* after creating the parser instead.

option_class (default: *optparse.Option*) Class to use when adding options to the parser in *add_option()*.

version (default: `None`) A version string to print when the user supplies a version option. If you supply a true value for version, *optparse* automatically adds a version option with the single option string `--version`. The substring %prog is expanded the same as for usage.

conflict_handler (default: "error") Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

description (default: `None`) A paragraph of text giving a brief overview of your program. *optparse* reformats this paragraph to fit the current terminal width and prints it when the user requests help (after usage, but before the list of options).

formatter (default: a new `IndentedHelpFormatter`) An instance of `optparse.HelpFormatter` that will be used for printing help text. `optparse` provides two concrete classes for this purpose: `IndentedHelpFormatter` and `TitledHelpFormatter`.

add_help_option (default: `True`) If true, `optparse` will add a help option (with option strings `-h` and `--help`) to the parser.

prog The string to use when expanding `%prog` in usage and version instead of `os.path.basename(sys.argv[0])`.

epilog (default: `None`) A paragraph of help text to print after the option help.

Populating the parser

There are several ways to populate the parser with options. The preferred way is by using `OptionParser.add_option()`, as shown in section *Tutorial*. `add_option()` can be called in one of two ways:

- pass it an `Option` instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the `Option` constructor), and it will create the `Option` instance for you

The other alternative is to pass a list of pre-constructed `Option` instances to the `OptionParser` constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating `Option` instances; currently it is an alias for the `Option` constructor. A future version of `optparse` may split `Option` into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate `Option` directly.)

Defining options

Each `Option` instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an `Option` instance is with the `add_option()` method of `OptionParser`.

`OptionParser.add_option(option)`

`OptionParser.add_option(*opt_str, attr=value, ...)`

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new `Option` object. The most important option attribute is `action`, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, `optparse` raises an `OptionError` exception explaining your mistake.

An option's *action* determines what *optparse* does when it encounters this option on the command-line. The standard option actions hard-coded into *optparse* are:

"store" store this option's argument (default)

"store_const" store a constant value

"store_true" store a true value

"store_false" store a false value

"append" append this option's argument to a list

"append_const" append a constant value to a list

"count" increment a counter by one

"callback" call a specified function

"help" print a usage message including all options and the documentation for them

(If you don't supply an action, the default is "store". For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called *options* (it happens to be an instance of *optparse.Values*). Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

For example, when you call

```
parser.parse_args()
```

one of the first things *optparse* does is create the *options* object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following:

```
-ffoo
-f foo
--file=foo
--file foo
```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

Option attributes

The following option attributes may be passed as keyword arguments to *OptionParser.add_option()*. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, *optparse* raises *OptionError*.

Option.action

(default: "store")

Determines *optparse*'s behaviour when this option is seen on the command line; the available options are documented [here](#).

Option.type

(default: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

Option.dest

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells *optparse* where to write it: *dest* names an attribute of the *options* object that *optparse* builds as it parses the command line.

Option.default

The value to use for this option's destination if the option is not seen on the command line. See also *OptionParser.set_defaults()*.

Option.nargs

(default: 1)

How many arguments of type *type* should be consumed when this option is seen. If > 1, *optparse* will store a tuple of values to *dest*.

Option.const

For actions that store a constant value, the constant value to store.

Option.choices

For options of type "choice", the list of strings the user may choose from.

Option.callback

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

Option.callback_args

Option.callback_kwargs

Additional positional and keyword arguments to pass to *callback* after the four standard callback arguments.

Option.help

Help text to print for this option when listing all available options after the user supplies a *help* option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value *optparse.SUPPRESS_HELP*.

Option.metavar

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [Tutorial](#) for an example.

Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide *optparse*'s behaviour; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the *Standard option types* section.

If *choices* is supplied (a list or tuple of strings), the type defaults to "choice".

If *type* is not supplied, it defaults to "string".

If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., `-f` implies `f`).

Example:

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

optparse will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store_const" [required: *const*; relevant: *dest*]

The value *const* is stored in *dest*.

Example:

```
parser.add_option("-q", "--quiet",
                  action="store_const", const=0, dest="verbose")
parser.add_option("-v", "--verbose",
                  action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                  action="store_const", const=2, dest="verbose")
```

If `--noisy` is seen, *optparse* will set

```
options.verbose = 2
```

- "store_true" [relevant: *dest*]

A special case of "store_const" that stores a true value to *dest*.

- "store_false" [relevant: *dest*]

Like "store_true", but stores a false value.

Example:

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

The defaults for *type* and *dest* are the same as for the "store" action.

Example:

```
parser.add_option("-t", "--tracks", action="append", type="int")
```

If `-t3` is seen on the command-line, *optparse* does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The `append` action calls the `append` method on the current value of the option. This means that any default value specified must have an `append` method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", default=['~/mypkg/defaults'])
>>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
>>> opts.files
['~/mypkg/defaults', 'overrides.mypkg']
```

- "append_const" [required: *const*; relevant: *dest*]

Like "store_const", but the value *const* is appended to *dest*; as with "append", *dest* defaults to None, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: *dest*]

Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.

Example:

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, *optparse* does the equivalent of:

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- "callback" [required: *callback*; relevant: *type*, *nargs*, *callback_args*, *callback_kwargs*]

Call the function specified by *callback*, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

See section *Option Callbacks* for more detail.

- "help"

Prints a complete help message for all the options in the current option parser. The help message is constructed from the usage string passed to *OptionParser*'s constructor and the *help* string passed to every option.

If no *help* string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

optparse automatically adds a *help* option to all `OptionParsers`, so you do not normally need to create one.

Example:

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If *optparse* sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]

Options:
  -h, --help            Show this help message and exit
  -v                    Be moderately verbose
  --file=FILENAME       Input file to read data from
```

After printing the help message, *optparse* terminates your process with `sys.exit(0)`.

- "version"

Prints the version number supplied to the `OptionParser` to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with *help* options, you will rarely create `version` options, since *optparse* automatically adds them when needed.

Standard option types

optparse has six built-in option types: `"string"`, `"int"`, `"long"`, `"choice"`, `"float"` and `"complex"`. If you need to add new option types, see section [Extending optparse](#).

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"` or `"long"`) are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling either `int()` or `long()` with the appropriate base (2, 8, 10, or 16). If this fails, so will *optparse*, although with a more useful error message.

"float" and "complex" option arguments are converted directly with `float()` and `complex()`, with similar error-handling.

"choice" options are a subtype of "string" options. The `choices` option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises `OptionValueError` if an invalid string is given.

Parsing arguments

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method:

```
(options, args) = parser.parse_args(args=None, values=None)
```

where the input parameters are

args the list of arguments to process (default: `sys.argv[1:]`)

values an `optparse.Values` object to store option arguments in (default: a new instance of `Values`) – if you give an existing object, the option defaults will not be initialized on it

and the return values are

options the same object that was passed in as `values`, or the `optparse.Values` instance created by `optparse`

args the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply `values`, it will be modified with repeated `setattr()` calls (roughly one for every option argument stored to an option destination) and returned by `parse_args()`.

If `parse_args()` encounters any errors in the argument list, it calls the `OptionParser`'s `error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out:

`OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, `optparse` normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call `disable_interspersed_args()`. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

`OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string `opt_str`, or `None` if no options have that option string.

`OptionParser.has_option(opt_str)`

Return true if the `OptionParser` has an option with option string `opt_str` (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to `opt_str`, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If `opt_str` does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, `optparse` checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

"error" (default) assume option conflicts are a programming error and raise `OptionConflictError`

"resolve" resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously-added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy    be noisy
```

It's possible to whittle away the option strings for a previously-added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, `optparse` removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser`:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so `optparse` removes it, leaving this help text:

```
Options:
...
-n, --noisy    be noisy
--dry-run      new dry-run option
```

Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

Other methods

`OptionParser` supports several other public methods:

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.print_usage(file=None)`

Print the usage message for the current program (`self.usage`) to `file` (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as `print_usage()` but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest=value, ...)`

Set default values for several option destinations at once. Using `set_defaults()` is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several “mode” options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")    # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")  # overrides above setting
```

To avoid this confusion, use `set_defaults()`:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

15.5.4 Option Callbacks

When *optparse*'s built-in actions and types aren't quite enough for your needs, you have two choices: extend *optparse* or define a callback option. Extending *optparse* is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

Defining a callback option

As always, the easiest way to define a callback option is by using the *OptionParser.add_option()* method. Apart from *action*, the only option attribute you must specify is *callback*, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

callback is a function (or other callable object), so you must have already defined *my_callback()* when you create this callback option. In this simple case, *optparse* doesn't even know if *-c* takes any arguments, which usually means that the option takes no arguments—the mere presence of *-c* on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

optparse always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via *callback_args* and *callback_kwargs*. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

type has its usual meaning: as with the "store" or "append" actions, it instructs *optparse* to consume one argument and convert it to *type*. Rather than storing the converted value(s) anywhere, though, *optparse* passes it to your callback function.

nargs also has its usual meaning: if it is supplied and *> 1*, *optparse* will consume *nargs* arguments, each of which must be convertible to *type*. It then passes a tuple of converted values to your callback.

callback_args a tuple of extra positional arguments to pass to the callback

callback_kwargs a dictionary of extra keyword arguments to pass to the callback

How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

option is the Option instance that's calling the callback

opt_str is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, *opt_str* will be the full, canonical option string—e.g. if the user puts *--foo* on the command-line as an abbreviation for *--foobar*, then *opt_str* will be *"--foobar"*.)

value is the argument to this option seen on the command-line. `optparse` will only expect an argument if `type` is set; the type of `value` will be the type implied by the option's type. If `type` for this option is `None` (no argument expected), then `value` will be `None`. If `nargs > 1`, `value` will be a tuple of values of the appropriate type.

parser is the `OptionParser` instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

parser.largs the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of `parse_args()`.)

parser.rargs the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

parser.values the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of `optparse` for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

args is a tuple of arbitrary positional arguments supplied via the `callback_args` option attribute.

kwargs is a dictionary of arbitrary keyword arguments supplied via `callback_kwargs`.

Raising errors in a callback

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). `optparse` catches this and terminates the program, printing the error message you supply to `stderr`. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the `"store_true"` action.

Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
    ...

parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

Callback example 3: check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

Callback example 4: check arbitrary condition

Of course, you could put any condition in there—you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                                % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon, dest="foo")
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define `type`, then the option takes one argument that must be convertible to that type; if you further define `nargs`, then the option takes `nargs` arguments.

Here's an example that just emulates the standard "store" action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that `optparse` takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as `optparse` doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies

of conventional Unix command-line parsing that *optparse* normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why *optparse* doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)
```

15.5.5 Extending *optparse*

Since the two major controlling factors in how *optparse* interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

Adding new types

To add new types, you need to define your own subclass of *optparse*'s `Option` class. This class has a couple of attributes that define *optparse*'s types: `TYPES` and `TYPE_CHECKER`.

`Option.TYPES`

A tuple of type names; in your subclass, simply define a new tuple `TYPES` that builds on the standard one.

`Option.TYPE_CHECKER`

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where `option` is an `Option` instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the `OptionValues` instance returned by `OptionParser.parse_args()`, or be passed to a callback as the `value` parameter.

Your type-checking function should raise `OptionValueError` if it encounters any problems. `OptionValueError` takes a single string argument, which is passed as-is to `OptionParser`'s `error()` method, which in turn prepends the program name and the string `"error: "` and prints everything to `stderr` before terminating the process.

Here's a silly example that demonstrates adding a `"complex"` option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because `optparse` 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the `TYPE_CHECKER` class attribute of your `Option` subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the `Option` subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a `copy()` of `Option.TYPE_CHECKER`, we would end up modifying the `TYPE_CHECKER` attribute of `optparse`'s `Option` class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to instruct your `OptionParser` to use `MyOption` instead of `Option`:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to `OptionParser`; if you don't use `add_option()` in the above way, you don't need to tell `OptionParser` which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

Adding new actions

Adding new actions is a bit trickier, because you have to understand that *optparse* has a couple of classifications for actions:

“store” actions actions that result in *optparse* storing a value to an attribute of the current *OptionValues* instance; these options require a *dest* attribute to be supplied to the *Option* constructor.

“typed” actions actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a *type* attribute to the *Option* constructor.

These are overlapping sets: some default “store” actions are "store", "store_const", "append", and "count", while the default “typed” actions are "store", "append", and "callback".

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of *Option* (all are lists of strings):

Option.**ACTIONS**

All actions must be listed in **ACTIONS**.

Option.**STORE_ACTIONS**

“store” actions are additionally listed here.

Option.**TYPED_ACTIONS**

“typed” actions are additionally listed here.

Option.**ALWAYS_TYPED_ACTIONS**

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that *optparse* assigns the default type, "string", to options with no explicit type whose action is listed in *ALWAYS_TYPED_ACTIONS*.

In order to actually implement your new action, you must override *Option*’s *take_action()* method and add a case that recognizes your action.

For example, let’s add an "extend" action. This is similar to the standard "append" action, but instead of taking a single value from the command-line and appending it to an existing list, "extend" will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if *--names* is an "extend" option of type "string", the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of *Option*:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
```

(continues on next page)

(continued from previous page)

```
Option.take_action(
    self, action, dest, opt, value, values, parser)
```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both `STORE_ACTIONS` and `TYPED_ACTIONS`.
- to ensure that `optparse` assigns the default type of "string" to "extend" actions, we put the "extend" action in `ALWAYS_TYPED_ACTIONS` as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard `optparse` actions.
- `values` is an instance of the `optparse_parser.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially `getattr()` with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the `attr` attribute of `values` doesn't exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns `value`. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

15.6 getopt — C-style parser for command line options

Source code: [Lib/getopt.py](#)

Note: The `getopt` module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the `argparse` module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form `'-'` and `'--'`). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(args, options[, long_options])`

Parses command line options and parameter list. `args` is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. `options` is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

Note: Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

`long_options`, if specified, must be a list of strings with the names of the long options which should be supported. The leading `'--'` characters should not be included in the option name. Long options which require an argument should

be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, *options* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *long_options* is ['foo', 'frob'], the option --fo will match as --foo, but --f will not match uniquely, so *GetoptError* will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt (args, options[, long_options])`

This function works like *getopt()*, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The *getopt()* function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

New in version 2.3.

exception `getopt.GetoptError`

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes *msg* and *opt* give the error message and related option; if there is no specific option to which the exception relates, *opt* is an empty string.

Changed in version 1.6: Introduced *GetoptError* as a synonym for *error*.

exception `getopt.error`

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print str(err) # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the `argparse` module:

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..
```

15.7 logging — Logging facility for Python

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial

- [Advanced Tutorial](#)
- [Logging Cookbook](#)

Source code: [Lib/logging/__init__.py](#)

New in version 2.3.

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to see the tutorials (see the links on the right).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

15.7.1 Logger Objects

Loggers have the following attributes and methods. Note that Loggers are never instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to `getLogger()` with the same name will always return a reference to the same Logger object.

The name is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class `logging.Logger`

`Logger.propagate`

If this evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

The constructor sets this attribute to `True`.

Note: If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

Logger.setLevel(*level*)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored. When a logger is created, the level is set to NOTSET (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level WARNING.

The term ‘delegation to the parent’ means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor’s level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root’s level will be used as the effective level.

See [Logging Levels](#) for a list of levels.

Logger.isEnabledFor(*lvl*)

Indicates if a message of severity *lvl* would be processed by this logger. This method checks first the module-level level set by `logging.disable(lvl)` and then the logger’s effective level as determined by `getEffectiveLevel()`.

Logger.getEffectiveLevel()

Indicates the effective level for this logger. If a value other than NOTSET has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than NOTSET is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

Logger.getChild(*suffix*)

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

New in version 2.7.

Logger.debug(*msg*, **args*, *kwargs*)**

Logs a message with level DEBUG on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are two keyword arguments in *kwargs* which are inspected: *exc_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

`Logger.info(msg, *args, **kwargs)`

Logs a message with level INFO on this logger. The arguments are interpreted as for *debug()*.

`Logger.warning(msg, *args, **kwargs)`

Logs a message with level WARNING on this logger. The arguments are interpreted as for *debug()*.

`Logger.error(msg, *args, **kwargs)`

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*.

`Logger.critical(msg, *args, **kwargs)`

Logs a message with level CRITICAL on this logger. The arguments are interpreted as for *debug()*.

`Logger.log(lvl, msg, *args, **kwargs)`

Logs a message with integer level *lvl* on this logger. The other arguments are interpreted as for *debug()*.

`Logger.exception(msg, *args, **kwargs)`

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*, except that any passed *exc_info* is not inspected. Exception info is always added to the logging message. This method should only be called from an exception handler.

`Logger.addFilter(filter)`

Adds the specified filter *filter* to this logger.

`Logger.removeFilter(filter)`

Removes the specified filter *filter* from this logger.

`Logger.filter(record)`

Applies this logger's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

`Logger.addHandler(hdlr)`

Adds the specified handler *hdlr* to this logger.

`Logger.removeHandler(hdlr)`

Removes the specified handler *hdlr* from this logger.

`Logger.findCaller()`

Finds the caller's source filename and line number. Returns the filename, line number and function name as a 3-element tuple.

Changed in version 2.4: The function name was added. In earlier versions, the filename and line number were returned as a 2-element tuple.

`Logger.handle(record)`

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using *filter()*.

`Logger.makeRecord` (*name*, *lvl*, *fn*, *lno*, *msg*, *args*, *exc_info*, *func=None*, *extra=None*)

This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

Changed in version 2.5: *func* and *extra* were added.

15.7.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

| Level | Numeric value |
|----------|---------------|
| CRITICAL | 50 |
| ERROR | 40 |
| WARNING | 30 |
| INFO | 20 |
| DEBUG | 10 |
| NOTSET | 0 |

15.7.3 Handler Objects

Handlers have the following attributes and methods. Note that `Handler` is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler.__init__()*.

`Handler.__init__` (*level=NOTSET*)

Initializes the `Handler` instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

`Handler.createLock` ()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

`Handler.acquire` ()

Acquires the thread lock created with *createLock()*.

`Handler.release` ()

Releases the thread lock acquired with *acquire()*.

`Handler.setLevel` (*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to NOTSET (which causes all messages to be processed).

See *Logging Levels* for a list of levels.

`Handler.setFormatter` (*fmt*)

Sets the *Formatter* for this handler to *fmt*.

`Handler.addFilter` (*filter*)

Adds the specified filter *filter* to this handler.

`Handler.removeFilter` (*filter*)

Removes the specified filter *filter* from this handler.

`Handler.filter` (*record*)

Applies this handler's filters to the record and returns a true value if the record is to be processed. The filters are

consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

`Handler.flush()`

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

`Handler.close()`

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when `shutdown()` is called. Subclasses should ensure that this gets called from overridden `close()` methods.

`Handler.handle(record)`

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

`Handler.handleError(record)`

This method should be called from handlers when an exception is encountered during an `emit()` call. If the module-level attribute `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

`Handler.format(record)`

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

`Handler.emit(record)`

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

For a list of handlers included as standard, see `logging.handlers`.

15.7.4 Formatter Objects

`Formatter` objects have the following attributes and methods. They are responsible for converting a `LogRecord` to (usually) a string which can be interpreted by either a human or an external system. The base `Formatter` allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the `LogRecord` attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a `LogRecord`'s `message` attribute. This format string contains standard Python %-style mapping keys. See section [String Formatting Operations](#) for more information on string formatting.

The useful mapping keys in a `LogRecord` are given in the section on [LogRecord attributes](#).

class `logging.Formatter` (*fmt=None*, *datefmt=None*)

Returns a new instance of the `Formatter` class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, the ISO8601 date format is used.

format (*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The `message` attribute of the record is computed using `msg % args`. If the formatting string contains `'(asctime)'`, `formatTime()` is called to format the event time. If there is exception information, it is formatted using

`formatException()` and appended to the message. Note that the formatted exception information is cached in attribute `exc_text`. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one `Formatter` subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value but recalculates it afresh.

formatTime (*record*, *datefmt=None*)

This method should be called from `format()` by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with `time.strftime()` to format the creation time of the record. Otherwise, the ISO8601 format is used. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, `time.localtime()` is used; to change this for a particular formatter instance, set the `converter` attribute to a function with the same signature as `time.localtime()` or `time.gmtime()`. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

formatException (*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by `sys.exc_info()`) as a string. This default implementation just uses `traceback.print_exception()`. The resulting string is returned.

15.7.5 Filter Objects

Filters can be used by Handlers and Loggers for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all events are passed.

class logging.**Filter** (*name=""*)

Returns an instance of the `Filter` class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter (*record*)

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using `debug()`, `info()`, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done with some care, but it does allow the injection of contextual information into logs (see filters-contextual).

15.7.6 LogRecord Objects

`LogRecord` instances are created automatically by the `Logger` every time something is logged, and can be created

manually via `makeLogRecord()` (for example, from a pickled event received over the wire).

class `logging.LogRecord` (*name, level, pathname, lineno, msg, args, exc_info, func=None*)
Contains all the information pertinent to the event being logged.

The primary information is passed in `msg` and `args`, which are combined using `msg % args` to create the message field of the record.

Parameters

- **name** – The name of the logger used to log the event represented by this `LogRecord`. Note that this name will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** – The numeric level of the logging event (one of `DEBUG`, `INFO` etc.) Note that this is converted to *two* attributes of the `LogRecord`: `levelname` for the numeric value and `levelname` for the corresponding level name.
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the `msg` argument to obtain the event description.
- **exc_info** – An exception tuple with the current exception information, or `None` if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.

Changed in version 2.5: `func` was added.

`getMessage()`

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

15.7.7 LogRecord attributes

The `LogRecord` has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the `LogRecord` constructor parameters and the `LogRecord` attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

| Attribute name | Format | Description |
|-----------------|---|--|
| args | You shouldn't need to format this yourself. | The tuple of arguments merged into <code>msg</code> to produce <code>message</code> , or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary). |
| asctime | <code>%(asctime)s</code> | Human-readable time when the <code>LogRecord</code> was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time). |
| created | <code>%(created)f</code> | Time when the <code>LogRecord</code> was created (as returned by <code>time.time()</code>). |
| exc_info | You shouldn't need to format this yourself. | Exception tuple (à la <code>sys.exc_info</code>) or, if no exception has occurred, <code>None</code> . |
| filename | <code>%(filename)s</code> | Filename portion of <code>pathname</code> . |
| funcName | <code>%(funcName)s</code> | Name of function containing the logging call. |
| levelname | <code>%(levelname)s</code> | Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL'). |
| levelno | <code>%(levelno)s</code> | Numeric logging level for the message (DEBUG, INFO, WARNING, ERROR, CRITICAL). |
| lineno | <code>%(lineno)d</code> | Source line number where the logging call was issued (if available). |
| module | <code>%(module)s</code> | Module (name portion of <code>filename</code>). |
| msecs | <code>%(msecs)d</code> | Millisecond portion of the time when the <code>LogRecord</code> was created. |
| message | <code>%(message)s</code> | The logged message, computed as <code>msg % args</code> . This is set when <code>Formatter.format()</code> is invoked. |
| msg | You shouldn't need to format this yourself. | The format string passed in the original logging call. Merged with <code>args</code> to produce <code>message</code> , or an arbitrary object (see arbitrary-object-messages). |
| name | <code>%(name)s</code> | Name of the logger used to log the call. |
| pathname | <code>%(pathname)s</code> | Full pathname of the source file where the logging call was issued (if available). |
| process | <code>%(process)d</code> | Process ID (if available). |
| processName | <code>%(processName)s</code> | Process name (if available). |
| relativeCreated | <code>%(relativeCreated)d</code> | Time in milliseconds when the <code>LogRecord</code> was created, relative to the time the logging module was loaded. |
| thread | <code>%(thread)d</code> | Thread ID (if available). |
| threadName | <code>%(threadName)s</code> | Thread name (if available). |

Changed in version 2.5: `funcName` was added.

Changed in version 2.6: `processName` was added.

15.7.8 LoggerAdapter Objects

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

New in version 2.6.

class logging.LoggerAdapter(*logger, extra*)

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance and a dict-like object.

process (*msg, kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg, kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()* and *isEnabledFor()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably for these calls.

Changed in version 2.7: The *isEnabledFor()* method was added to *LoggerAdapter*. This method delegates to the underlying logger.

15.7.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

15.7.10 Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

logging.getLogger(*[name]*)

Return a logger with the specified name or, if no name is specified, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like "a", "a.b" or "a.b.c.d". Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.getLoggerClass()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.debug(*msg[, *args[, **kwargs]]*)

Logs a message with level DEBUG on the root logger. The *msg* is the message format string, and the *args* are the

arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are two keyword arguments in *kwargs* which are inspected: *exc_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The other optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = "%(asctime)-15s %(clientip)s %(user)-8s %(message)s"
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning("Protocol problem: %s", "connection reset", extra=d)
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

Changed in version 2.5: *extra* was added.

`logging.info(msg[, *args[, **kwargs]])`

Logs a message with level INFO on the root logger. The arguments are interpreted as for `debug()`.

`logging.warning(msg[, *args[, **kwargs]])`

Logs a message with level WARNING on the root logger. The arguments are interpreted as for `debug()`.

`logging.error(msg[, *args[, **kwargs]])`

Logs a message with level ERROR on the root logger. The arguments are interpreted as for `debug()`.

`logging.critical(msg[, *args[, **kwargs]])`

Logs a message with level CRITICAL on the root logger. The arguments are interpreted as for `debug()`.

`logging.exception(msg[, *args[, **kwargs]])`

Logs a message with level ERROR on the root logger. The arguments are interpreted as for `debug()`, except that any passed *exc_info* is not inspected. Exception info is always added to the logging message. This function should only be called from an exception handler.

`logging.log(level, msg[, *args[, **kwargs]])`

Logs a message with level *level* on the root logger. The other arguments are interpreted as for `debug()`.

Note: The above module-level convenience functions, which delegate to the root logger, call `basicConfig()` to ensure that at least one handler is available. Because of this, they should *not* be used in threads, in versions of Python earlier than 2.7.1 and 3.2, unless at least one handler has been added to the root logger *before* the threads are started. In earlier versions of Python, due to a thread safety shortcoming in `basicConfig()`, this can (under

rare circumstances) lead to handlers being added multiple times to the root logger, which can in turn lead to multiple messages for the same event.

`logging.disable(lvl)`

Provides an overriding level *lvl* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *lvl* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

`logging.addLevelName(lvl, levelName)`

Associates level *lvl* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a *Formatter* formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

Note: If you are thinking of defining your own levels, please see the section on custom-levels.

`logging.getLevelName(lvl)`

Returns the textual representation of logging level *lvl*. If the level is one of the predefined levels CRITICAL, ERROR, WARNING, INFO or DEBUG then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with *lvl* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned. Otherwise, the string "Level %s" % *lvl* is returned.

Note: Integer levels should be used when e.g. setting levels on instances of *Logger* and handlers. This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see *LogRecord attributes*).

`logging.makeLogRecord(attrdict)`

Creates and returns a new *LogRecord* instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled *LogRecord* attribute dictionary, sent over a socket, and reconstituting it as a *LogRecord* instance at the receiving end.

`logging.basicConfig(**kwargs)`

Does basic configuration for the logging system by creating a *StreamHandler* with a default *Formatter* and adding it to the root logger. The functions `debug()`, `info()`, `warning()`, `error()` and `critical()` will call `basicConfig()` automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured for it.

Changed in version 2.4: Formerly, `basicConfig()` did not take any keyword arguments.

Note: This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

| Format | Description |
|-----------------|---|
| <i>filename</i> | Specifies that a <code>FileHandler</code> be created, using the specified filename, rather than a <code>StreamHandler</code> . |
| <i>filemode</i> | If <i>filename</i> is specified, open the file in this mode. Defaults to 'a'. |
| <i>format</i> | Use the specified format string for the handler. |
| <i>datefmt</i> | Use the specified date/time format, as accepted by <code>time.strftime()</code> . |
| <i>level</i> | Set the root logger level to the specified <i>level</i> . |
| <i>stream</i> | Use the specified stream to initialize the <code>StreamHandler</code> . Note that this argument is incompatible with <i>filename</i> - if both are present, <i>stream</i> is ignored. |

`logging.shutdown()`

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

`logging.setLoggerClass(klass)`

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior.

15.7.11 Integration with the warnings module

The `captureWarnings()` function can be used to integrate `logging` with the `warnings` module.

`logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named 'py.warnings' with a severity of `WARNING`.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

PEP 282 - A Logging System The proposal which described this feature for inclusion in the Python standard library.

Original Python logging package This is the original source for the `logging` package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the `logging` package in the standard library.

15.8 logging.config — Logging configuration

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial

Source code: [Lib/logging/config.py](#)

This section describes the API for configuring the logging module.

15.8.1 Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An `id` which does not have a corresponding destination.
- A non-existent handler `id` found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

`dictConfig()` calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then `dictConfig()` could be called exactly as in the default, uncusomized state.

New in version 2.7.

`logging.config.fileConfig(fname, defaults=None, disable_existing_loggers=True)`

Reads the logging configuration from a `configparser`-format file named `fname`. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

Parameters

- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable_existing_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing loggers unless they or their ancestors are explicitly named in the logging configuration.

Changed in version 2.6: The `disable_existing_loggers` keyword argument was added. Previously, existing loggers were *always* disabled.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

To send a configuration to the socket, read in the configuration file and send it to the socket as a string of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

Note: Because portions of the configuration are passed through `eval()`, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used).

`logging.config.stopListening()`

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

15.8.2 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding `Formatter` instance.

The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a `Formatter` instance.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a `logging.Filter` instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

The configuring dict is searched for the following keys:

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.
- `filters` (optional). A list of ids of the filters for this handler.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level  : INFO
    filters: [allow_foo]
    stream : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a `logging.StreamHandler`, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a `logging.handlers.RotatingFileHandler` with the keyword arguments `filename='logconfig.log'`, `maxBytes=1024`, `backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys:

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.
- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.

- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- *disable_existing_loggers* - whether any existing loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
```

(continues on next page)

(continued from previous page)

```
# other configuration for logger 'foo.bar.baz'
handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a 'factory' - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key '()' '. Here's a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

and:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key '()' , the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
    '()' : 'my.package.customFormatterFactory',
    'bar' : 'baz',
    'spam' : 99.9,
    'answer' : 42
}
```

and this contains the special key '()' , which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key '()' has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The '()' also serves as a mnemonic that the corresponding value is a callable.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+) :// (?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a level in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
    file:
```

(continues on next page)

(continued from previous page)

```
# configuration of file handler goes here

custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
    email:
        class: logging.handlers.SMTPHandler
        mailhost: localhost
        fromaddr: my_app@domain.tld
        toaddrs:
            - support_team@domain.tld
            - dev_team@domain.tld
        subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team.domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The subject value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

15.8.3 Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities

of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

Note: The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure `Filter` objects, which provide for filtering of messages beyond simple integer levels, using `fileConfig()`. If you need to have instances of `Filter` in your logging configuration, you will need to use `dictConfig()`. Note that future enhancements to configuration functionality will be added to `dictConfig()`, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *eval()*uated in the context of the logging package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
```

(continues on next page)

(continued from previous page)

```
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by `eval()` in the `logging` package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

Changed in version 2.6: Added support for resolving the handler's class as a dotted module and class name.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when `eval()` uated in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args= (('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
```

(continues on next page)

(continued from previous page)

```
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter
```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes ISO8601 format date/times, which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. The ISO8601 format also specifies milliseconds, which are appended to the result of using the above format string, with a comma separator. An example time in ISO8601 format is `2003-01-23 00:29:50,411`.

The `class` entry is optional. It indicates the name of the formatter's class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

Note: Due to the use of `eval()` as described above, there are potential security risks which result from using the `listen()` to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the `listen()` documentation for more information.

15.9 logging.handlers — Logging handlers

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

Source code: `Lib/logging/handlers.py`

The following useful handlers are provided in the package. Note that three of the handlers (*StreamHandler*, *FileHandler* and *NullHandler*) are actually defined in the *logging* module itself, but have been documented here along with the other handlers.

15.9.1 StreamHandler

The *StreamHandler* class, located in the core *logging* package, sends logging output to streams such as *sys.stdout*, *sys.stderr* or any file-like object (or, more precisely, any object which supports *write()* and *flush()* methods).

class *logging.StreamHandler* (*stream=None*)

Returns a new instance of the *StreamHandler* class. If *stream* is specified, the instance will use it for logging output; otherwise, *sys.stderr* will be used.

emit (*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream with a newline terminator. If exception information is present, it is formatted using *traceback.print_exception()* and appended to the stream.

flush ()

Flushes the stream by calling its *flush()* method. Note that the *close()* method is inherited from *Handler* and so does no output, so an explicit *flush()* call may be needed at times.

15.9.2 FileHandler

The *FileHandler* class, located in the core *logging* package, sends logging output to a disk file. It inherits the output functionality from *StreamHandler*.

class *logging.FileHandler* (*filename, mode='a', encoding=None, delay=False*)

Returns a new instance of the *FileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not *None*, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely.

Changed in version 2.6: *delay* was added.

close ()

Closes the file.

emit (*record*)

Outputs the record to the file.

15.9.3 NullHandler

New in version 2.7.

The *NullHandler* class, located in the core *logging* package, does not do any formatting or output. It is essentially a 'no-op' handler for use by library developers.

class *logging.NullHandler*

Returns a new instance of the *NullHandler* class.

emit (*record*)

This method does nothing.

handle (*record*)

This method does nothing.

createLock ()

This method returns *None* for the lock, since there is no underlying I/O to which access needs to be serialized.

See *library-config* for more information on how to use *NullHandler*.

15.9.4 WatchedFileHandler

New in version 2.6.

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

class `logging.handlers.WatchedFileHandler` (`filename`[, `mode`[, `encoding`[, `delay`]]])

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not None, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

emit (`record`)

Outputs the record to the file, but first checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, before outputting the record to the file.

15.9.5 RotatingFileHandler

The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

class `logging.handlers.RotatingFileHandler` (`filename`, `mode`='a', `maxBytes`=0, `backupCount`=0, `encoding`=None, `delay`=0)

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not None, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

You can use the `maxBytes` and `backupCount` values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly `maxBytes` in length; if either of `maxBytes` or `backupCount` is zero, rollover never occurs. If `backupCount` is non-zero, the system will save old log files by appending the extensions '.1', '.2' etc., to the filename. For example, with a `backupCount` of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

Changed in version 2.6: `delay` was added.

doRollover ()

Does a rollover, as described above.

emit (`record`)

Outputs the record to the file, catering for rollover as described previously.

15.9.6 TimedRotatingFileHandler

The *TimedRotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files at certain timed intervals.

class logging.handlers.**TimedRotatingFileHandler** (*filename*, *when='h'*, *interval=1*, *backupCount=0*, *encoding=None*, *delay=False*, *utc=False*)

Returns a new instance of the *TimedRotatingFileHandler* class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

| Value | Type of interval |
|------------|-----------------------|
| 'S' | Seconds |
| 'M' | Minutes |
| 'H' | Hours |
| 'D' | Days |
| 'W0'-'W6' | Weekday (0=Monday) |
| 'midnight' | Roll over at midnight |

When using weekday-based rotation, specify 'W0' for Monday, 'W1' for Tuesday, and so on up to 'W6' for Sunday. In this case, the value passed for *interval* isn't used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format %Y-%m-%d_%H-%M-%S or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to *emit()*.

Changed in version 2.6: *delay* and *utc* were added.

doRollover()

Does a rollover, as described above.

emit(record)

Outputs the record to the file, catering for rollover as described above.

15.9.7 SocketHandler

The *SocketHandler* class, located in the *logging.handlers* module, sends logging output to a network socket. The base class uses a TCP socket.

class logging.handlers.**SocketHandler** (*host*, *port*)

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

close()

Closes the socket.

emit ()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

handleError ()

Handles an error which has occurred during *emit()*. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket ()

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (*socket.SOCK_STREAM*).

makePickle (record)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket.

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send (packet)

Send a pickled string *packet* to the socket. This function allows for partial sends which can happen when the network is busy.

createSocket ()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- *retryStart* (initial delay, defaulting to 1.0 seconds).
- *retryFactor* (multiplier, defaulting to 2.0).
- *retryMax* (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

15.9.8 DatagramHandler

The *DatagramHandler* class, located in the *logging.handlers* module, inherits from *SocketHandler* to support sending logging messages over UDP sockets.

class logging.handlers.DatagramHandler (host, port)

Returns a new instance of the *DatagramHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

emit ()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

makeSocket()

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK_DGRAM*).

send(s)

Send a pickled string to a socket.

15.9.9 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

class *logging.handlers.SysLogHandler* (*address*=('localhost', *SYSLOG_UDP_PORT*), *facility*=*LOG_USER*, *socketype*=*socket.SOCK_DGRAM*)

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a (*host*, *port*) tuple. If *address* is not specified, ('localhost', 514) is used. The address is used to open a socket. An alternative to providing a (*host*, *port*) tuple is providing an address as a string, for example '/dev/log'. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, *LOG_USER* is used. The type of socket opened depends on the *socketype* argument, which defaults to *socket.SOCK_DGRAM* and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of *socket.SOCK_STREAM*.

Note that if your server is not listening on UDP port 514, *SysLogHandler* may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually '/dev/log' but on OS/X it's '/var/run/syslog'. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

Changed in version 2.7: *socketype* was added.

close()

Closes the socket to the remote host.

emit(record)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

encodePriority(facility, priority)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic *LOG_* values are defined in *SysLogHandler* and mirror the values defined in the *sys/syslog.h* header file.

Priorities

| Name (string) | Symbolic value |
|------------------|----------------|
| alert | LOG_ALERT |
| crit or critical | LOG_CRIT |
| debug | LOG_DEBUG |
| emerg or panic | LOG_EMERG |
| err or error | LOG_ERR |
| info | LOG_INFO |
| notice | LOG_NOTICE |
| warn or warning | LOG_WARNING |

Facilities

| Name (string) | Symbolic value |
|---------------|----------------|
| auth | LOG_AUTH |
| authpriv | LOG_AUTHPRIV |
| cron | LOG_CRON |
| daemon | LOG_DAEMON |
| ftp | LOG_FTP |
| kern | LOG_KERN |
| lpr | LOG_LPR |
| mail | LOG_MAIL |
| news | LOG_NEWS |
| syslog | LOG_SYSLOG |
| user | LOG_USER |
| uucp | LOG_UUCP |
| local0 | LOG_LOCAL0 |
| local1 | LOG_LOCAL1 |
| local2 | LOG_LOCAL2 |
| local3 | LOG_LOCAL3 |
| local4 | LOG_LOCAL4 |
| local5 | LOG_LOCAL5 |
| local6 | LOG_LOCAL6 |
| local7 | LOG_LOCAL7 |

mapPriority (*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps DEBUG, INFO, WARNING, ERROR and CRITICAL to the equivalent syslog names, and all other level names to 'warning'.

15.9.10 NTEventLogHandler

The *NTEventLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

class *logging.handlers.NTEventLogHandler* (*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *NTEventLogHandler* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

close ()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit (*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory (*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This

version returns 0.

getEventType (*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's `typemap` attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's `typemap` attribute.

getMessageID (*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

15.9.11 SMTPHandler

The *SMTPHandler* class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

class `logging.handlers.SMTPHandler` (*mailhost, fromaddr, toaddrs, subject, credentials=None, secure=None*)

Returns a new instance of the *SMTPHandler* class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the `smtplib.SMTP.starttls()` method.)

Changed in version 2.6: *credentials* was added.

Changed in version 2.7: *secure* was added.

emit (*record*)

Formats the record and sends it to the specified addressees.

getSubject (*record*)

If you want to specify a subject line which is record-dependent, override this method.

15.9.12 MemoryHandler

The *MemoryHandler* class, located in the `logging.handlers` module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general *BufferingHandler*, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

class `logging.handlers.BufferingHandler` (*capacity*)

Initializes the handler with a buffer of the specified capacity.

emit (*record*)

Appends the record to the buffer. If `shouldFlush()` returns true, calls `flush()` to process the buffer.

flush()

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

shouldFlush(record)

Returns true if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.**MemoryHandler**(*capacity, flushLevel=ERROR, target=None*)

Returns a new instance of the *MemoryHandler* class. The instance is initialized with a buffer size of *capacity*. If *flushLevel* is not specified, *ERROR* is used. If no *target* is specified, the target will need to be set using *setTarget()* before this handler does anything useful.

close()

Calls *flush()*, sets the target to *None* and clears the buffer.

flush()

For a *MemoryHandler*, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

setTarget(target)

Sets the target handler for this handler.

shouldFlush(record)

Checks for buffer full or a record at the *flushLevel* or higher.

15.9.13 HTTPHandler

The *HTTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to a Web server, using either GET or POST semantics.

class logging.handlers.**HTTPHandler**(*host, url, method='GET'*)

Returns a new instance of the *HTTPHandler* class. The *host* can be of the form *host:port*, should you need to use a specific port number.

mapLogRecord(record)

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns *record.__dict__*. This method can be overridden if e.g. only a subset of *LogRecord* is to be sent to the web server, or if more specific customization of what's sent to the server is required.

emit(record)

Sends the record to the Web server as a URL-encoded dictionary. The *mapLogRecord()* method is used to convert the record to the dictionary to be sent.

Note: Since preparing a record for sending it to a Web server is not the same as a generic formatting operation, using *setFormatter()* to specify a *Formatter* for a *HTTPHandler* has no effect. Instead of calling *format()*, this handler calls *mapLogRecord()* and then *urllib.urlencode()* to encode the dictionary in a form suitable for sending to a Web server.

Module *logging* API reference for the logging module.

Module *logging.config* Configuration API for the logging module.

15.10 `getpass` — Portable password input

The `getpass` module provides two functions:

`getpass.getpass([prompt[, stream]])`

Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to 'Password: '. On Unix, the prompt is written to the file-like object *stream*. *stream* defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable `getpass()` falls back to printing a warning message to *stream* and reading from `sys.stdin` and issuing a `GetPassWarning`.

Changed in version 2.5: The *stream* parameter was added.

Changed in version 2.6: On Unix it defaults to using `/dev/tty` before falling back to `sys.stdin` and `sys.stderr`.

Note: If you call `getpass` from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

exception `getpass.GetPassWarning`

A `UserWarning` subclass issued when password input may be echoed.

`getpass.getuser()`

Return the “login name” of the user.

This function checks the environment variables `LOGNAME`, `USER`, `LNAME` and `USERNAME`, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the `pwd` module, otherwise, an exception is raised.

15.11 `curses` — Terminal handling for character-cell displays

Changed in version 1.6: Added support for the `ncurses` library and converted to a package.

The `curses` module provides an interface to the `curses` library, the de-facto standard for portable advanced terminal handling.

While `curses` is most widely used in the Unix environment, versions are available for DOS, OS/2, and possibly other systems as well. This extension module is designed to match the API of `ncurses`, an open-source `curses` library hosted on Linux and the BSD variants of Unix.

Note: Since version 5.4, the `ncurses` library decides how to interpret non-ASCII data using the `nl_langinfo` function. That means that you have to call `locale.setlocale()` in the application and encode Unicode strings using one of the system’s available encodings. This example uses the system’s default encoding:

```
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

Then use *code* as the encoding for `str.encode()` calls.

Module `curses.ascii` Utilities for working with ASCII characters, regardless of your locale settings.

Module `curses.panel` A panel stack extension that adds depth to curses windows.

Module `curses.textpad` Editable text widget for curses supporting **Emacs**-like bindings.

curses-howto Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The `Demo/curses/` directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

15.11.1 Functions

The module `curses` defines the following exception:

exception `curses.error`

Exception raised when a curses library function returns an error.

Note: Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

The module `curses` defines the following functions:

`curses.baudrate()`

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

`curses.beep()`

Emit a short attention sound.

`curses.can_change_color()`

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

`curses.cbreak()`

Enter cbreak mode. In cbreak mode (sometimes called “rare” mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in cbreak mode.

`curses.color_content(color_number)`

Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between 0 and `COLORS`. A 3-tuple is returned, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

`curses.color_pair(color_number)`

Return the attribute value for displaying text in the specified color. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

`curses.curs_set(visibility)`

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, the previous cursor state is returned; otherwise, an exception is raised. On many terminals, the “visible” mode is an underline cursor and the “very visible” mode is a block cursor.

`curses.def_prog_mode()`

Save the current terminal mode as the “program” mode, the mode when the running program is using curses. (Its counterpart is the “shell” mode, for when the program is not in curses.) Subsequent calls to `reset_prog_mode()` will restore this mode.

`curses.def_shell_mode()`

Save the current terminal mode as the “shell” mode, the mode when the running program is not using curses. (Its counterpart is the “program” mode, when the program is using curses capabilities.) Subsequent calls to `reset_shell_mode()` will restore this mode.

`curses.delay_output(ms)`

Insert an *ms* millisecond pause in output.

`curses.doupdate()`

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The `doupdate()` ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a `noutrefresh()` call after write operations such as `addstr()` have been performed on a window. The normal `refresh()` call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

`curses.echo()`

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

`curses.endwin()`

De-initialize the library, and return terminal to normal status.

`curses.erasechar()`

Return the user’s current erase character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.filter()`

The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, `LINES` is set to 1; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the home string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

`curses.flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as ‘visible bell’ to the audible attention signal produced by `beep()`.

`curses.flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

`curses.getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be call to retrieve the queued mouse event, represented as a 5-tuple (*id*, *x*, *y*, *z*, *bstate*). *id* is an ID value used to distinguish multiple devices, and *x*, *y*, *z* are the event’s coordinates. (*z* is currently unused.) *bstate* is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where *n* is the button number from 1 to 4: `BUTTONn_PRESSED`, `BUTTONn_RELEASED`, `BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`, `BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`, `BUTTON_CTRL`, `BUTTON_ALT`.

`curses.getsyx()`

Return the current coordinates of the virtual screen cursor in *y* and *x*. If `leaveok` is currently true, then -1,-1 is returned.

`curses.getwin(file)`

Read window related data stored in the file by an earlier `putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.has_colors()`

Return True if the terminal can display colors; otherwise, return False.

`curses.has_ic()`

Return True if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_il()`

Return True if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_key(ch)`

Take a key value *ch*, and return True if the current terminal type recognizes a key with that value.

`curses.halfdelay(tenths)`

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, an exception is raised if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

`curses.init_color(color_number, r, g, b)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between 0 and COLORS. Each of *r*, *g*, *b*, must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns 1.

`curses.init_pair(pair_number, fg, bg)`

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between 1 and COLOR_PAIRS - 1 (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and COLORS. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.initscr()`

Initialize the library. Return a `WindowObject` which represents the whole screen.

Note: If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

`curses.is_term_resized(nlines, ncols)`

Return True if `resize_term()` would modify the window structure, False otherwise.

`curses.isendwin()`

Return True if `endwin()` has been called (that is, the curses library has been deinitialized).

`curses.keyname(k)`

Return the name of the key numbered *k*. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-character string consisting of a caret followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a string consisting of the prefix 'M-' followed by the name of the corresponding ASCII character.

`curses.killchar()`

Return the user's current line kill character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.longname()`

Return a string containing the terminfo long name field describing the current terminal. The maximum length of a

verbose description is 128 characters. It is defined only after the call to `initscr()`.

`curses.meta` (*yes*)

If *yes* is 1, allow 8-bit characters to be input. If *yes* is 0, allow only 7-bit chars.

`curses.mouseinterval` (*interval*)

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 msec, or one fifth of a second.

`curses.mousemask` (*mousemask*)

Set the mouse events to be reported, and return a tuple (*availmask*, *oldmask*). *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns 0. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

`curses.napms` (*ms*)

Sleep for *ms* milliseconds.

`curses.newpad` (*nlines*, *ncols*)

Create and return a pointer to a new pad data structure with the given number of lines and columns. A pad is returned as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The `refresh()` and `noutrefresh()` methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

`curses.newwin` (*nlines*, *ncols*)

`curses.newwin` (*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a new window, whose left-upper corner is at (*begin_y*, *begin_x*), and whose height/width is *nlines/ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

`curses.nl` ()

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

`curses.nocbreak` ()

Leave cbreak mode. Return to normal “cooked” mode with line buffering.

`curses.noecho` ()

Leave echo mode. Echoing of input characters is turned off.

`curses.nonl` ()

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

`curses.noqiflush` ()

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

`curses.noraw` ()

Leave raw mode. Return to normal “cooked” mode with line buffering.

`curses.pair_content(pair_number)`

Return a tuple (fg, bg) containing the colors for the requested color pair. The value of *pair_number* must be between 1 and `COLOR_PAIRS - 1`.

`curses.pair_number(attr)`

Return the number of the color-pair set by the attribute value *attr*. `color_pair()` is the counterpart to this function.

`curses.putp(string)`

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of `putp()` always goes to standard output.

`curses.qiflush([flag])`

If *flag* is False, the effect is the same as calling `noqiflush()`. If *flag* is True, or no argument is provided, the queues will be flushed when these control characters are read.

`curses.raw()`

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

`curses.reset_prog_mode()`

Restore the terminal to “program” mode, as previously saved by `def_prog_mode()`.

`curses.reset_shell_mode()`

Restore the terminal to “shell” mode, as previously saved by `def_shell_mode()`.

`curses.resetty()`

Restore the state of the terminal modes to what it was at the last call to `savetty()`.

`curses.resize_term(nlines, ncols)`

Backend function used by `resizeterm()`, performing most of the work; when resizing the windows, `resize_term()` blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The `resize_term()` function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

`curses.resizeterm(nlines, ncols)`

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

`curses.savetty()`

Save the current state of the terminal modes in a buffer, usable by `resetty()`.

`curses.setsyx(y, x)`

Set the virtual screen cursor to y, x. If y and x are both -1, then leaveok is set.

`curses.setupterm([termstr, fd])`

Initialize the terminal. *termstr* is a string giving the terminal name; if omitted, the value of the `TERM` environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied, the file descriptor for `sys.stdout` will be used.

`curses.start_color()`

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after `initscr()`.

`start_color()` initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the `curses` module, `COLORS` and `COLOR_PAIRS`, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

`curses.termattrs()`

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses

program needs complete control over the appearance of the screen.

`curses.termname()`

Return the value of the environment variable `TERM`, truncated to 14 characters.

`curses.tigetflag(capname)`

Return the value of the Boolean capability corresponding to the terminfo capability name *capname*. The value `-1` is returned if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

`curses.tigetnum(capname)`

Return the value of the numeric capability corresponding to the terminfo capability name *capname*. The value `-2` is returned if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

`curses.tigetstr(capname)`

Return the value of the string capability corresponding to the terminfo capability name *capname*. `None` is returned if *capname* is not a string capability, or is canceled or absent from the terminal description.

`curses.tparm(str[, ...])`

Instantiate the string *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `'\033[6;4H'`, the exact result depending on terminal type.

`curses.typeahead(fd)`

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh` or `doupdate` is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

`curses.unctrl(ch)`

Return a string which is a printable representation of the character *ch*. Control characters are displayed as a caret followed by the character, for example as `^C`. Printing characters are left as they are.

`curses.ungetch(ch)`

Push *ch* so the next `getch()` will return it.

Note: Only one *ch* can be pushed before `getch()` is called.

`curses.ungetmouse(id, x, y, z, bstate)`

Push a `KEY_MOUSE` event onto the input queue, associating the given state data with it.

`curses.use_env(flag)`

If used, this function should be called before `initscr()` or `newterm` are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

`curses.use_default_colors()`

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair *x* to a red foreground color on the default background.

`curses.wrapper(func, ...)`

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window `'stdscr'` as its first argument, followed by any other arguments passed to `wrapper()`. Before calling *func*, `wrapper()` turns on

`cbreak` mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

15.11.2 Window Objects

Window objects, as returned by `initscr()` and `newwin()` above, have the following methods:

```
window.addch(ch[, attr])
window.addch(y, x, ch[, attr])
```

Note: A *character* means a C character (an ASCII code), rather than a Python character (a string of length 1). (This note is true whenever the documentation mentions a character.) The built-in `ord()` is handy for conveying strings to codes.

Paint character *ch* at (*y*, *x*) with attributes *attr*, overwriting any character previously painter at that location. By default, the character position and attributes are the current settings for the window object.

Note: Writing outside the window, subwindow, or pad raises a `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

```
window.addnstr(str, n[, attr])
window.addnstr(y, x, str, n[, attr])
```

Paint at most *n* characters of the string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

```
window.addstr(str[, attr])
window.addstr(y, x, str[, attr])
```

Paint the string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

Note: Writing outside the window, subwindow, or pad raises `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.

```
window.attroff(attr)
```

Remove attribute *attr* from the “background” set applied to all writes to the current window.

```
window.attron(attr)
```

Add attribute *attr* from the “background” set applied to all writes to the current window.

```
window.attrset(attr)
```

Set the “background” set of attributes to *attr*. This set is initially 0 (no attributes).

```
window.bkgd(ch[, attr])
```

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

```
window.bkgdset(ch[, attr])
```

Set the window’s background. A window’s background consists of a character and any combination of attributes.

The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border` (`[ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]]`)

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details. The characters can be specified as integers or as one-character strings.

Note: A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

| Parameter | Description | Default value |
|-----------|---------------------|---------------|
| <i>ls</i> | Left side | ACS_VLINE |
| <i>rs</i> | Right side | ACS_VLINE |
| <i>ts</i> | Top | ACS_HLINE |
| <i>bs</i> | Bottom | ACS_HLINE |
| <i>tl</i> | Upper-left corner | ACS_ULCORNER |
| <i>tr</i> | Upper-right corner | ACS_URCORNER |
| <i>bl</i> | Bottom-left corner | ACS_LLCORNER |
| <i>br</i> | Bottom-right corner | ACS_LRCORNER |

`window.box` (`[vertch, horch]`)

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat` (*attr*)

`window.chgat` (*num*, *attr*)

`window.chgat` (*y*, *x*, *attr*)

`window.chgat` (*y*, *x*, *num*, *attr*)

Set the attributes of *num* characters at the current cursor position, or at position (*y*, *x*) if supplied. If *num* is not given or is -1, the attribute will be set on all the characters to the end of the line. This function moves cursor to position (*y*, *x*) if supplied. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

`window.clear` ()

Like `erase()`, but also cause the whole window to be repainted upon next call to `refresh()`.

`window.clearok` (*yes*)

If *yes* is 1, the next call to `refresh()` will clear the window completely.

`window.clrtoebot` ()

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

`window.clrtoeol` ()

Erase from cursor to the end of the line.

`window.cursyncup` ()

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.delch` (`[y, x]`)

Delete any character at (*y*, *x*).

`window.deleteln()`

Delete the line under the cursor. All following lines are moved up by one line.

`window.derwin(begin_y, begin_x)`

`window.derwin(nlines, ncols, begin_y, begin_x)`

An abbreviation for “derive window”, `derwin()` is the same as calling `subwin()`, except that `begin_y` and `begin_x` are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

`window.echochar(ch[, attr])`

Add character `ch` with attribute `attr`, and immediately call `refresh()` on the window.

`window.enclose(y, x)`

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning True or False. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

`window.erase()`

Clear the window.

`window.getbegyx()`

Return a tuple `(y, x)` of co-ordinates of upper-left corner.

`window.getbkgd()`

Return the given window’s current background character/attribute pair.

`window.getch([y, x])`

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on return numbers higher than 256. In no-delay mode, -1 is returned if there is no input, else `getch()` waits until a key is pressed.

`window.getkey([y, x])`

Get a character, returning a string instead of an integer, as `getch()` does. Function keys, keypad keys and so on return a multibyte string containing the key name. In no-delay mode, an exception is raised if there is no input.

`window.getmaxyx()`

Return a tuple `(y, x)` of the height and width of the window.

`window.getparyx()`

Return the beginning coordinates of this window relative to its parent window into two integer variables `y` and `x`. Return -1, -1 if this window has no parent.

`window.getstr([y, x])`

Read a string from the user, with primitive line editing capacity.

`window.getyx()`

Return a tuple `(y, x)` of current cursor position relative to the window’s upper-left corner.

`window.hline(ch, n)`

`window.hline(y, x, ch, n)`

Display a horizontal line starting at `(y, x)` with length `n` consisting of the character `ch`.

`window.idcok(flag)`

If `flag` is False, `curses` no longer considers using the hardware insert/delete character feature of the terminal; if `flag` is True, use of character insertion and deletion is enabled. When `curses` is first initialized, use of character insert/delete is enabled by default.

`window.idlok(yes)`

If called with `yes` equal to 1, `curses` will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call `refresh()` yourself. However, it may degrade performance considerably, due to repeated calls to `wrefresh`. This option is disabled by default.

`window.inch([y, x])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch(ch[, attr])`

`window.insch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, moving the line from position *x* right by one character.

`window.insdelln(nlines)`

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

`window.insertln()`

Insert a blank line under the cursor. All following lines are moved down by one line.

`window.insnstr(str, n[, attr])`

`window.insnstr(y, x, str, n[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.insstr(str[, attr])`

`window.insstr(y, x, str[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.instr([n])`

`window.instr(y, x[, n])`

Return a string of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, `instr()` returns a string at most *n* characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`

Return `True` if the specified line was modified since the last call to `refresh()`; otherwise return `False`. Raise a `curses.error` exception if *line* is not valid for the given window.

`window.is_wintouched()`

Return `True` if the specified window was modified since the last call to `refresh()`; otherwise return `False`.

`window.keypad(yes)`

If *yes* is 1, escape sequences generated by some keys (keypad, function keys) will be interpreted by `curses`. If *yes* is 0, escape sequences will be left as is in the input stream.

`window.leaveok(yes)`

If *yes* is 1, cursor is left where it is on update, instead of being at “cursor position.” This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *yes* is 0, cursor will always be at “cursor position” after an update.

`window.move(new_y, new_x)`

Move cursor to (*new_y*, *new_x*).

`window.mvderwin(y, x)`

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

`window.mvwin(new_y, new_x)`

Move the window so its upper-left corner is at `(new_y, new_x)`.

`window.nodelay(yes)`

If `yes` is 1, `getch()` will be non-blocking.

`window.notimeout(yes)`

If `yes` is 1, escape sequences will not be timed out.

If `yes` is 0, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

`window.noutrefresh()`

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call `doupdate()`.

`window.overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overlay the window on top of `destwin`. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of `destwin`.

To get fine-grained control over the copied region, the second form of `overlay()` can be used. `sminrow` and `smincol` are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

`window.overwrite(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overwrite the window on top of `destwin`. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of `destwin`.

To get fine-grained control over the copied region, the second form of `overwrite()` can be used. `sminrow` and `smincol` are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

`window.putwin(file)`

Write all data associated with the window into the provided file object. This information can be later retrieved using the `getwin()` function.

`window.redrawln(beg, num)`

Indicate that the `num` screen lines, starting at line `beg`, are corrupted and should be completely redrawn on the next `refresh()` call.

`window.redrawwin()`

Touch the entire window, causing it to be completely redrawn on the next `refresh()` call.

`window.refresh([pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol])`

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with `newpad()`. The additional parameters are needed to indicate what part of the pad and screen are involved. `pminrow` and `pmincol` specify the upper left-hand corner of the rectangle to be displayed in the pad. `sminrow`, `smincol`, `smaxrow`, and `smaxcol` specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of `pminrow`, `pmincol`, `sminrow`, or `smincol` are treated as if they were zero.

`window.resize(nlines, ncols)`

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by `bkgdset()`) merged into them.

`window.scroll([lines=1])`

Scroll the screen or scrolling region upward by *lines* lines.

`window.scrollok(flag)`

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is false, the cursor is left on the bottom line. If *flag* is true, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.

`window.setscrreg(top, bottom)`

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

`window.standend()`

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

`window.standout()`

Turn on attribute `A_STANDOUT`.

`window.subpad(begin_y, begin_x)`

`window.subpad(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

`window.subwin(begin_y, begin_x)`

`window.subwin(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

`window.syncdown()`

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by `refresh()`, so it should almost never be necessary to call it manually.

`window.syncok(flag)`

If called with *flag* set to True, then `syncup()` is called automatically whenever there is a change in the window.

`window.syncup()`

Touch all locations in ancestors of the window that have been changed in the window.

`window.timeout(delay)`

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and -1 will be returned by `getch()` if no input is waiting. If *delay* is positive, then `getch()` will block for *delay* milliseconds, and return -1 if there is still no input at the end of that time.

`window.touchline(start, count[, changed])`

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=1) or unchanged (*changed*=0).

`window.touchwin()`

Pretend the whole window has been changed, for purposes of drawing optimizations.

`window.untouchwin()`

Mark all lines in the window as unchanged since the last call to `refresh()`.

`window.vline(ch, n)`

`window.vline(y, x, ch, n)`

Display a vertical line starting at (y, x) with length n consisting of the character ch .

15.11.3 Constants

The `curses` module defines the following data members:

`curses.ERR`

Some curses routines that return an integer, such as `getch()`, return `ERR` upon failure.

`curses.OK`

Some curses routines that return an integer, such as `napms()`, return `OK` upon success.

`curses.version`

A string representing the current version of the module. Also available as `__version__`.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

| Attribute | Meaning |
|---------------------------|--|
| <code>A_ALTCHARSET</code> | Alternate character set mode |
| <code>A_BLINK</code> | Blink mode |
| <code>A_BOLD</code> | Bold mode |
| <code>A_DIM</code> | Dim mode |
| <code>A_INVIS</code> | Invisible or blank mode |
| <code>A_NORMAL</code> | Normal attribute |
| <code>A_PROTECT</code> | Protected mode |
| <code>A_REVERSE</code> | Reverse background and foreground colors |
| <code>A_STANDOUT</code> | Standout mode |
| <code>A_UNDERLINE</code> | Underline mode |
| <code>A_HORIZONTAL</code> | Horizontal highlight |
| <code>A_LEFT</code> | Left highlight |
| <code>A_LOW</code> | Low highlight |
| <code>A_RIGHT</code> | Right highlight |
| <code>A_TOP</code> | Top highlight |
| <code>A_VERTICAL</code> | Vertical highlight |
| <code>A_CHARTEXT</code> | Bit-mask to extract a character |

Several constants are available to extract corresponding attributes returned by some methods.

| Bit-mask | Meaning |
|---------------------------|--|
| <code>A_ATTRIBUTES</code> | Bit-mask to extract attributes |
| <code>A_CHARTEXT</code> | Bit-mask to extract a character |
| <code>A_COLOR</code> | Bit-mask to extract color-pair field information |

Keys are referred to by integer constants with names starting with `KEY_`. The exact keycaps available are system dependent.

| Key constant | Key |
|------------------------|------------------------|
| <code>KEY_MIN</code> | Minimum key value |
| <code>KEY_BREAK</code> | Break key (unreliable) |
| <code>KEY_DOWN</code> | Down-arrow |
| <code>KEY_UP</code> | Up-arrow |

Continued on next page

Table 1 – continued from previous page

| Key constant | Key |
|---------------|--|
| KEY_LEFT | Left-arrow |
| KEY_RIGHT | Right-arrow |
| KEY_HOME | Home key (upward+left arrow) |
| KEY_BACKSPACE | Backspace (unreliable) |
| KEY_F0 | Function keys. Up to 64 function keys are supported. |
| KEY_Fn | Value of function key <i>n</i> |
| KEY_DL | Delete line |
| KEY_IL | Insert line |
| KEY_DC | Delete character |
| KEY_IC | Insert char or enter insert mode |
| KEY_EIC | Exit insert char mode |
| KEY_CLEAR | Clear screen |
| KEY_EOS | Clear to end of screen |
| KEY_EOL | Clear to end of line |
| KEY_SF | Scroll 1 line forward |
| KEY_SR | Scroll 1 line backward (reverse) |
| KEY_NPAGE | Next page |
| KEY_PPAGE | Previous page |
| KEY_STAB | Set tab |
| KEY_CTAB | Clear tab |
| KEY_CATAB | Clear all tabs |
| KEY_ENTER | Enter or send (unreliable) |
| KEY_SRESET | Soft (partial) reset (unreliable) |
| KEY_RESET | Reset or hard reset (unreliable) |
| KEY_PRINT | Print |
| KEY_LL | Home down or bottom (lower left) |
| KEY_A1 | Upper left of keypad |
| KEY_A3 | Upper right of keypad |
| KEY_B2 | Center of keypad |
| KEY_C1 | Lower left of keypad |
| KEY_C3 | Lower right of keypad |
| KEY_BTAB | Back tab |
| KEY_BEG | Beg (beginning) |
| KEY_CANCEL | Cancel |
| KEY_CLOSE | Close |
| KEY_COMMAND | Cmd (command) |
| KEY_COPY | Copy |
| KEY_CREATE | Create |
| KEY_END | End |
| KEY_EXIT | Exit |
| KEY_FIND | Find |
| KEY_HELP | Help |
| KEY_MARK | Mark |
| KEY_MESSAGE | Message |
| KEY_MOVE | Move |
| KEY_NEXT | Next |
| KEY_OPEN | Open |
| KEY_OPTIONS | Options |
| KEY_PREVIOUS | Prev (previous) |

Continued on next page

Table 1 – continued from previous page

| Key constant | Key |
|---------------|--------------------------|
| KEY_REDO | Redo |
| KEY_REFERENCE | Ref (reference) |
| KEY_REFRESH | Refresh |
| KEY_REPLACE | Replace |
| KEY_RESTART | Restart |
| KEY_RESUME | Resume |
| KEY_SAVE | Save |
| KEY_SBEG | Shifted Beg (beginning) |
| KEY_SCANCEL | Shifted Cancel |
| KEY_SCOMMAND | Shifted Command |
| KEY_SCOPY | Shifted Copy |
| KEY_SCREATE | Shifted Create |
| KEY_SDC | Shifted Delete char |
| KEY_SDL | Shifted Delete line |
| KEY_SELECT | Select |
| KEY_SEND | Shifted End |
| KEY_SEOL | Shifted Clear line |
| KEY_SEXIT | Shifted Exit |
| KEY_SFIND | Shifted Find |
| KEY_SHELP | Shifted Help |
| KEY_SHOME | Shifted Home |
| KEY_SIC | Shifted Input |
| KEY_SLEFT | Shifted Left arrow |
| KEY_SMESSAGE | Shifted Message |
| KEY_SMOVE | Shifted Move |
| KEY_SNEXT | Shifted Next |
| KEY_SOPTIONS | Shifted Options |
| KEY_SPREVIOUS | Shifted Prev |
| KEY_SPRINT | Shifted Print |
| KEY_SREDO | Shifted Redo |
| KEY_SREPLACE | Shifted Replace |
| KEY_SRIGHT | Shifted Right arrow |
| KEY_SRSUME | Shifted Resume |
| KEY_SSAVE | Shifted Save |
| KEY_SSUSPEND | Shifted Suspend |
| KEY_SUNDO | Shifted Undo |
| KEY_SUSPEND | Suspend |
| KEY_UNDO | Undo |
| KEY_MOUSE | Mouse event has occurred |
| KEY_RESIZE | Terminal resize event |
| KEY_MAX | Maximum key value |

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (KEY_F1, KEY_F2, KEY_F3, KEY_F4) available, and the arrow keys mapped to KEY_UP, KEY_DOWN, KEY_LEFT and KEY_RIGHT in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

| Keycap | Constant |
|-----------|-----------|
| Insert | KEY_IC |
| Delete | KEY_DC |
| Home | KEY_HOME |
| End | KEY_END |
| Page Up | KEY_PPAGE |
| Page Down | KEY_NPAGE |

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

Note: These are available only after `initscr()` has been called.

| ACS code | Meaning |
|--------------|---------------------------------------|
| ACS_BBSS | alternate name for upper right corner |
| ACS_BLOCK | solid square block |
| ACS_BOARD | board of squares |
| ACS_BSBS | alternate name for horizontal line |
| ACS_BSSB | alternate name for upper left corner |
| ACS_BSSS | alternate name for top tee |
| ACS_BTEE | bottom tee |
| ACS_BULLET | bullet |
| ACS_CKBOARD | checker board (stipple) |
| ACS_DARROW | arrow pointing down |
| ACS_DEGREE | degree symbol |
| ACS_DIAMOND | diamond |
| ACS_GEQUAL | greater-than-or-equal-to |
| ACS_HLINE | horizontal line |
| ACS_LANTERN | lantern symbol |
| ACS_LARROW | left arrow |
| ACS_LEQUAL | less-than-or-equal-to |
| ACS_LLCORNER | lower left-hand corner |
| ACS_LRCORNER | lower right-hand corner |
| ACS_LTEE | left tee |
| ACS_NEQUAL | not-equal sign |
| ACS_PI | letter pi |
| ACS_PLMINUS | plus-or-minus sign |
| ACS_PLUS | big plus sign |
| ACS_RARROW | right arrow |
| ACS_RTEE | right tee |
| ACS_S1 | scan line 1 |
| ACS_S3 | scan line 3 |
| ACS_S7 | scan line 7 |
| ACS_S9 | scan line 9 |
| ACS_SBBS | alternate name for lower right corner |
| ACS_SBSB | alternate name for vertical line |
| ACS_SBSS | alternate name for right tee |
| ACS_SSBB | alternate name for lower left corner |

Continued on next page

Table 2 – continued from previous page

| ACS code | Meaning |
|--------------|--|
| ACS_SSBS | alternate name for bottom tee |
| ACS_SSSB | alternate name for left tee |
| ACS_SSSS | alternate name for crossover or big plus |
| ACS_STERLING | pound sterling |
| ACS_TTEE | top tee |
| ACS_UARROW | up arrow |
| ACS_ULCORNER | upper left corner |
| ACS_URCORNER | upper right corner |
| ACS_VLINE | vertical line |

The following table lists the predefined colors:

| Constant | Color |
|---------------|----------------------------|
| COLOR_BLACK | Black |
| COLOR_BLUE | Blue |
| COLOR_CYAN | Cyan (light greenish blue) |
| COLOR_GREEN | Green |
| COLOR_MAGENTA | Magenta (purplish red) |
| COLOR_RED | Red |
| COLOR_WHITE | White |
| COLOR_YELLOW | Yellow |

15.12 `curses.textpad` — Text input widget for curses programs

New in version 1.6.

The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function:

`curses.textpad.rectangle` (*win*, *uly*, *ulx*, *lry*, *lrx*)

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

15.12.1 Textbox objects

You can instantiate a `Textbox` object as follows:

class `curses.textpad.Textbox` (*win*)

Return a textbox widget object. The *win* argument should be a curses `WindowObject` in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates (0, 0). The instance's `stripspaces` flag is initially on.

`Textbox` objects have the following methods:

edit ([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

do_command (*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

| Keystroke | Action |
|-----------|---|
| Control-A | Go to left edge of window. |
| Control-B | Cursor left, wrapping to previous line if appropriate. |
| Control-D | Delete character under cursor. |
| Control-E | Go to right edge (stripspaces off) or end of line (stripspaces on). |
| Control-F | Cursor right, wrapping to next line when appropriate. |
| Control-G | Terminate, returning the window contents. |
| Control-H | Delete character backward. |
| Control-J | Terminate if the window is 1 line, otherwise insert newline. |
| Control-K | If line is blank, delete it, otherwise clear to end of line. |
| Control-L | Refresh screen. |
| Control-N | Cursor down; move down one line. |
| Control-O | Insert a blank line at cursor location. |
| Control-P | Cursor up; move up one line. |

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

| Constant | Keystroke |
|---------------|-----------|
| KEY_LEFT | Control-B |
| KEY_RIGHT | Control-F |
| KEY_UP | Control-P |
| KEY_DOWN | Control-N |
| KEY_BACKSPACE | Control-h |

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather ()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

15.13 `curses.ascii` — Utilities for ASCII characters

New in version 1.6.

The *curses.ascii* module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

| Name | Meaning |
|------|---|
| NUL | |
| SOH | Start of heading, console interrupt |
| STX | Start of text |
| ETX | End of text |
| EOT | End of transmission |
| ENQ | Enquiry, goes with ACK flow control |
| ACK | Acknowledgement |
| BEL | Bell |
| BS | Backspace |
| TAB | Tab |
| HT | Alias for TAB: “Horizontal tab” |
| LF | Line feed |
| NL | Alias for LF: “New line” |
| VT | Vertical tab |
| FF | Form feed |
| CR | Carriage return |
| SO | Shift-out, begin alternate character set |
| SI | Shift-in, resume default character set |
| DLE | Data-link escape |
| DC1 | XON, for flow control |
| DC2 | Device control 2, block-mode flow control |
| DC3 | XOFF, for flow control |
| DC4 | Device control 4 |
| NAK | Negative acknowledgement |
| SYN | Synchronous idle |
| ETB | End transmission block |
| CAN | Cancel |
| EM | End of medium |
| SUB | Substitute |
| ESC | Escape |
| FS | File separator |
| GS | Group separator |
| RS | Record separator, block-mode terminator |
| US | Unit separator |
| SP | Space |
| DEL | Delete |

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

`curses.ascii.isalnum(c)`

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c)` or `isdigit(c)`.

`curses.ascii.isalpha(c)`

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.

`curses.ascii.isascii(c)`

Checks for a character value that fits in the 7-bit ASCII set.

`curses.ascii.isblank(c)`

Checks for an ASCII whitespace character; space or horizontal tab.

`curses.ascii.iscntrl(c)`

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

`curses.ascii.isdigit(c)`

Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to `c in string.digits`.

`curses.ascii.isgraph(c)`

Checks for ASCII any printable character except space.

`curses.ascii.islower(c)`

Checks for an ASCII lower-case character.

`curses.ascii.isprint(c)`

Checks for any ASCII printable character including space.

`curses.ascii.ispunct(c)`

Checks for any printable ASCII character which is not a space or an alphanumeric character.

`curses.ascii.isspace(c)`

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

`curses.ascii.isupper(c)`

Checks for an ASCII uppercase letter.

`curses.ascii.isxdigit(c)`

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

`curses.ascii.isctrl(c)`

Checks for an ASCII control character (ordinal values 0 to 31).

`curses.ascii.ismeta(c)`

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the first character of the string you pass in; they do not actually know anything about the host machine's character encoding. For functions that know about the character encoding (and handle internationalization properly) see the *string* module.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

`curses.ascii.ascii(c)`

Return the ASCII value corresponding to the low 7 bits of *c*.

`curses.ascii.ctrl(c)`

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

`curses.ascii.alt(c)`

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

`curses.ascii.unctrl(c)`

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret ('^') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

`curses.ascii.controlnames`

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

15.14 `curses.panel` — A panel stack extension for `curses`

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

15.14.1 Functions

The module `curses.panel` defines the following functions:

`curses.panel.bottom_panel()`

Returns the bottom panel in the panel stack.

`curses.panel.new_panel(win)`

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

`curses.panel.top_panel()`

Returns the top panel in the panel stack.

`curses.panel.update_panels()`

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

15.14.2 Panel Objects

Panel objects, as returned by `new_panel()` above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

`Panel.above()`

Returns the panel above the current panel.

`Panel.below()`

Returns the panel below the current panel.

`Panel.bottom()`

Push the panel to the bottom of the stack.

`Panel.hidden()`

Returns true if the panel is hidden (not visible), false otherwise.

`Panel.hide()`

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

`Panel.move(y, x)`

Move the panel to the screen coordinates (*y*, *x*).

`Panel.replace(win)`

Change the window associated with the panel to the window *win*.

`Panel.set_userptr(obj)`

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`

Display the panel (which might have been hidden).

`Panel.top()`

Push panel to the top of the stack.

`Panel.userptr()`

Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`

Returns the window object associated with the panel.

15.15 platform — Access to underlying platform's identifying data

New in version 2.3.

Source code: [Lib/platform.py](#)

Note: Specific platforms listed alphabetically, with Linux included in the Unix section.

15.15.1 Cross Platform

`platform.architecture(executable=sys.executable, bits="", linkage="")`

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple (*bits*, *linkage*) which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If *bits* is given as '', the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

Note: On Mac OS X (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the “64-bitness” of the current interpreter, it is more reliable to query the `sys.maxsize` attribute:

```
is_64bits = sys.maxsize > 2**32
```

`platform.machine()`

Returns the machine type, e.g. 'i386'. An empty string is returned if the value cannot be determined.

`platform.node()`

Returns the computer's network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

`platform.platform(aliased=0, terse=0)`

Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The `system_alias()` function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

`platform.processor()`

Returns the (real) processor name, e.g. 'amd64'.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for `machine()`. NetBSD does this.

`platform.python_build()`

Returns a tuple (buildno, builddate) stating the Python build number and date as strings.

`platform.python_compiler()`

Returns a string identifying the compiler used for compiling Python.

`platform.python_branch()`

Returns a string identifying the Python implementation SCM branch.

New in version 2.6.

`platform.python_implementation()`

Returns a string identifying the Python implementation. Possible return values are: 'CPython', 'IronPython', 'Jython', 'PyPy'.

New in version 2.6.

`platform.python_revision()`

Returns a string identifying the Python implementation SCM revision.

New in version 2.6.

`platform.python_version()`

Returns the Python version as string 'major.minor.patchlevel'.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

`platform.python_version_tuple()`

Returns the Python version as tuple (major, minor, patchlevel) of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to '0').

`platform.release()`

Returns the system's release, e.g. '2.2.0' or 'NT'. An empty string is returned if the value cannot be determined.

`platform.system()`

Returns the system/OS name, e.g. 'Linux', 'Windows', or 'Java'. An empty string is returned if the value cannot be determined.

`platform.system_alias(system, release, version)`

Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

`platform.version()`

Returns the system's release version, e.g. `'#3 on degas'`. An empty string is returned if the value cannot be determined.

`platform.uname()`

Fairly portable `uname` interface. Returns a tuple of strings (`system`, `node`, `release`, `version`, `machine`, `processor`) identifying the underlying platform.

Note that unlike the `os.uname()` function this also returns possible processor information as additional tuple entry.

Entries which cannot be determined are set to `' '`.

15.15.2 Java Platform

`platform.java_ver(release="", vendor="", vminfo=("", ""), osinfo=("", ""))`

Version interface for Jython.

Returns a tuple (`release`, `vendor`, `vminfo`, `osinfo`) with `vminfo` being a tuple (`vm_name`, `vm_release`, `vm_vendor`) and `osinfo` being a tuple (`os_name`, `os_version`, `os_arch`). Values which cannot be determined are set to the defaults given as parameters (which all default to `' '`).

15.15.3 Windows Platform

`platform.win32_ver(release="", version="", csd="", ptype="")`

Get additional version information from the Windows Registry and return a tuple (`release`, `version`, `csd`, `ptype`) referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor).

As a hint: `ptype` is `'Uniprocessor Free'` on single processor NT machines and `'Multiprocessor Free'` on multi processor machines. The `'Free'` refers to the OS version being free of debugging code. It could also state `'Checked'` which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

Note: This function works best with Mark Hammond's `win32all` package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

Win95/98 specific

`platform.popen(cmd, mode='r', bufsize=None)`

Portable `popen()` interface. Find a working `popen` implementation preferring `win32pipe.popen()`. On Windows NT, `win32pipe.popen()` should work; on Windows 9x it hangs due to bugs in the MS C library.

15.15.4 Mac OS Platform

`platform.mac_ver(release="", versioninfo=("", ""), machine="")`

Get Mac OS version information and return it as tuple (`release`, `versioninfo`, `machine`) with `versioninfo` being a tuple (`version`, `dev_stage`, `non_release_version`).

Entries which cannot be determined are set to `' '`. All tuple entries are strings.

15.15.5 Unix Platforms

`platform.dist (distname="", version="", id="", supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...))`

This is an old version of the functionality now provided by `linux_distribution()`. For new code, please use the `linux_distribution()`.

The only difference between the two is that `dist()` always returns the short name of the distribution taken from the `supported_dists` parameter.

Deprecated since version 2.6.

`platform.linux_distribution (distname="", version="", id="", supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...), full_distribution_name=1)`

Tries to determine the name of the Linux OS distribution name.

`supported_dists` may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If `full_distribution_name` is `true` (default), the full distribution read from the OS is returned. Otherwise the short name taken from `supported_dists` is used.

Returns a tuple (`distname`, `version`, `id`) which defaults to the args given as parameters. `id` is the item in parentheses after the version number. It is usually the version codename.

Note: This function is deprecated since Python 3.5 and removed in Python 3.8. See alternative like the [distro](#) package.

New in version 2.6.

`platform.libc_ver (executable=sys.executable, lib="", version="", chunksize=2048)`

Tries to determine the libc version against which the file `executable` (defaults to the Python interpreter) is linked. Returns a tuple of strings (`lib`, `version`) which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using **gcc**.

The file is read and scanned in chunks of `chunksize` bytes.

15.16 `errno` — Standard `errno` system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

`errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`

Operation not permitted

`errno.ENOENT`

No such file or directory

`errno.ESRCH`
No such process

`errno.EINTR`
Interrupted system call

`errno.EIO`
I/O error

`errno.ENXIO`
No such device or address

`errno.E2BIG`
Arg list too long

`errno.ENOEXEC`
Exec format error

`errno.EBADF`
Bad file number

`errno.ECHILD`
No child processes

`errno.EAGAIN`
Try again

`errno.ENOMEM`
Out of memory

`errno.EACCES`
Permission denied

`errno.EFAULT`
Bad address

`errno.ENOTBLK`
Block device required

`errno.EBUSY`
Device or resource busy

`errno.EEXIST`
File exists

`errno.EXDEV`
Cross-device link

`errno.ENODEV`
No such device

`errno.ENOTDIR`
Not a directory

`errno.EISDIR`
Is a directory

`errno.EINVAL`
Invalid argument

`errno.ENFILE`
File table overflow

`errno.EMFILE`
Too many open files

`errno.ENOTTY`
Not a typewriter

`errno.ETXTBSY`
Text file busy

`errno.EFBIG`
File too large

`errno.ENOSPC`
No space left on device

`errno.ESPIPE`
Illegal seek

`errno.EROFS`
Read-only file system

`errno.EMLINK`
Too many links

`errno.EPIPE`
Broken pipe

`errno.EDOM`
Math argument out of domain of func

`errno.ERANGE`
Math result not representable

`errno.EDEADLK`
Resource deadlock would occur

`errno.ENAMETOOLONG`
File name too long

`errno.ENOLCK`
No record locks available

`errno.ENOSYS`
Function not implemented

`errno.ENOTEMPTY`
Directory not empty

`errno.ELOOP`
Too many symbolic links encountered

`errno.EWOULDBLOCK`
Operation would block

`errno.ENOMSG`
No message of desired type

`errno.EIDRM`
Identifier removed

`errno.ECHRNG`
Channel number out of range

`errno.EL2NSYNC`
Level 2 not synchronized

`errno.EL3HLT`
Level 3 halted

`errno.EL3RST`
Level 3 reset

`errno.ELNRNG`
Link number out of range

`errno.EUNATCH`
Protocol driver not attached

`errno.ENOCSI`
No CSI structure available

`errno.EL2HLT`
Level 2 halted

`errno.EBADE`
Invalid exchange

`errno.EBADR`
Invalid request descriptor

`errno.EXFULL`
Exchange full

`errno.ENOANO`
No anode

`errno.EBADRQC`
Invalid request code

`errno.EBADSLT`
Invalid slot

`errno.EDEADLOCK`
File locking deadlock error

`errno.EBFONT`
Bad font file format

`errno.ENOSTR`
Device not a stream

`errno.ENODATA`
No data available

`errno.ETIME`
Timer expired

`errno.ENOSR`
Out of streams resources

`errno.ENONET`
Machine is not on the network

`errno.ENOPKG`
Package not installed

`errno.EREMOTE`
Object is remote

`errno.ENOLINK`
Link has been severed

`errno.EADV`
Advertise error

`errno.ESRMNT`
Srmount error

`errno.ECOMM`
Communication error on send

`errno.EPROTO`
Protocol error

`errno.EMULTIHOP`
Multihop attempted

`errno.EDOTDOT`
RFS specific error

`errno.EBADMSG`
Not a data message

`errno.EOVERFLOW`
Value too large for defined data type

`errno.ENOTUNIQ`
Name not unique on network

`errno.EBADFD`
File descriptor in bad state

`errno.EREMCHG`
Remote address changed

`errno.ELIBACC`
Can not access a needed shared library

`errno.ELIBBAD`
Accessing a corrupted shared library

`errno.ELIBSCN`
.lib section in a.out corrupted

`errno.ELIBMAX`
Attempting to link in too many shared libraries

`errno.ELIBEXEC`
Cannot exec a shared library directly

`errno.EILSEQ`
Illegal byte sequence

`errno.ERESTART`
Interrupted system call should be restarted

`errno.ESTRPIPE`
Streams pipe error

`errno.EUSERS`
Too many users

`errno.ENOTSOCK`
Socket operation on non-socket

`errno.EDESTADDRREQ`
Destination address required

`errno.EMSGSIZE`
Message too long

`errno.EPROTOTYPE`
Protocol wrong type for socket

`errno.ENOPROTOOPT`
Protocol not available

`errno.EPROTONOSUPPORT`
Protocol not supported

`errno.ESOCKTNOSUPPORT`
Socket type not supported

`errno.EOPNOTSUPP`
Operation not supported on transport endpoint

`errno.EPFNOSUPPORT`
Protocol family not supported

`errno.EAFNOSUPPORT`
Address family not supported by protocol

`errno.EADDRINUSE`
Address already in use

`errno.EADDRNOTAVAIL`
Cannot assign requested address

`errno.ENETDOWN`
Network is down

`errno.ENETUNREACH`
Network is unreachable

`errno.ENETRESET`
Network dropped connection because of reset

`errno.ECONNABORTED`
Software caused connection abort

`errno.ECONNRESET`
Connection reset by peer

`errno.ENOBUFS`
No buffer space available

`errno.EISCONN`
Transport endpoint is already connected

`errno.ENOTCONN`
Transport endpoint is not connected

`errno.ESHUTDOWN`
Cannot send after transport endpoint shutdown

`errno.ETOOMANYREFS`
Too many references: cannot splice

`errno.ETIMEDOUT`
Connection timed out

`errno.ECONNREFUSED`
Connection refused

`errno.EHOSTDOWN`
Host is down

`errno.EHOSTUNREACH`
No route to host

`errno.EALREADY`
Operation already in progress

`errno.EINPROGRESS`
Operation now in progress

`errno.ESTALE`
Stale NFS file handle

`errno.EUCLEAN`
Structure needs cleaning

`errno.ENOTNAM`
Not a XENIX named type file

`errno.ENAVAIL`
No XENIX semaphores available

`errno.EISNAM`
Is a named type file

`errno.EREMOTEIO`
Remote I/O error

`errno.EDQUOT`
Quota exceeded

15.17 ctypes — A foreign function library for Python

New in version 2.5.

`ctypes` is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

15.17.1 ctypes tutorial

Note: The code samples in this tutorial use `doctest` to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or Mac OS X, they contain doctest directives in comments.

Note: Some code samples reference the ctypes `c_int` type. This type is an alias for the `c_long` type on 32-bit systems. So, you should not be confused if `c_long` is printed if you would expect `c_int` — they are actually the same type.

Loading dynamic link libraries

`ctypes` exports the `cdll`, and on Windows `windll` and `oledll` objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. `cdll` loads libraries which export functions using the standard `cdecl` calling convention, while `windll` libraries call functions using the `stdcall` calling convention. `oledll` also uses the `stdcall` calling convention, and assumes the functions return a Windows `HRESULT` error code. The error code is used to automatically raise a `WindowsError` exception when the function call fails.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the `cdecl` calling convention:

```
>>> from ctypes import *
>>> print windll.kernel32
<WinDLL 'kernel32', handle ... at ...>
>>> print cdll.msvcrt
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print windll.kernel32.GetModuleHandleA
<_FuncPtr object at 0x...>
>>> print windll.kernel32.MyOwnFunction
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with strings or unicode strings respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use `getattr()` to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a NULL pointer (None should be used as the NULL pointer):

```
>>> print libc.time(None)
1150640792
>>> print hex(windll.kernel32.GetModuleHandleA(None))
0x1d000000
>>>
```

ctypes tries to protect you from calling functions with the wrong number of arguments or the wrong calling convention. Unfortunately this only works on Windows. It does this by examining the stack after the function returns, so although an error is raised the function *has* been called:

```
>>> windll.kernel32.GetModuleHandleA()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>> windll.kernel32.GetModuleHandleA(0, 0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

The same exception is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>>

>>> windll.msvcrt.printf("spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, *ctypes* uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
WindowsError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with *ctypes*, so you should be careful anyway.

None, integers, longs, byte strings and unicode strings are the only native Python objects that can directly be used as parameters in these function calls. None is passed as a C NULL pointer, byte strings and unicode strings are passed as pointer to the memory block that contains their data (char * or wchar_t *). Python integers and Python longs are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about *ctypes* data types.

Fundamental data types

ctypes defines a number of primitive C compatible data types:

| ctypes type | C type | Python type |
|---------------------------|--|--|
| <code>c_bool</code> | <code>_Bool</code> | <code>bool</code> (1) |
| <code>c_char</code> | <code>char</code> | 1-character string |
| <code>c_wchar</code> | <code>wchar_t</code> | 1-character unicode string |
| <code>c_byte</code> | <code>char</code> | <code>int/long</code> |
| <code>c_ubyte</code> | <code>unsigned char</code> | <code>int/long</code> |
| <code>c_short</code> | <code>short</code> | <code>int/long</code> |
| <code>c_ushort</code> | <code>unsigned short</code> | <code>int/long</code> |
| <code>c_int</code> | <code>int</code> | <code>int/long</code> |
| <code>c_uint</code> | <code>unsigned int</code> | <code>int/long</code> |
| <code>c_long</code> | <code>long</code> | <code>int/long</code> |
| <code>c_ulong</code> | <code>unsigned long</code> | <code>int/long</code> |
| <code>c_longlong</code> | <code>__int64</code> or <code>long long</code> | <code>int/long</code> |
| <code>c_ulonglong</code> | <code>unsigned __int64</code> or <code>unsigned long long</code> | <code>int/long</code> |
| <code>c_float</code> | <code>float</code> | <code>float</code> |
| <code>c_double</code> | <code>double</code> | <code>float</code> |
| <code>c_longdouble</code> | <code>long double</code> | <code>float</code> |
| <code>c_char_p</code> | <code>char *</code> (NUL terminated) | <code>string</code> or <code>None</code> |
| <code>c_wchar_p</code> | <code>wchar_t *</code> (NUL terminated) | <code>unicode</code> or <code>None</code> |
| <code>c_void_p</code> | <code>void *</code> | <code>int/long</code> or <code>None</code> |

(1) The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_char_p("Hello, World")
c_char_p('Hello, World')
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```
>>> i = c_int(42)
>>> print i
c_long(42)
>>> print i.value
42
>>> i.value = -99
>>> print i.value
-99
>>>
```

Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python strings are immutable):

```
>>> s = "Hello, World"
>>> c_s = c_char_p(s)
>>> print c_s
c_char_p('Hello, World')
>>> c_s.value = "Hi, there"
>>> print c_s
c_char_p('Hi, there')
```

(continues on next page)

(continued from previous page)

```
>>> print s                # first string is unchanged
Hello, World
>>>
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```
>>> from ctypes import *
>>> p = create_string_buffer(3)      # create a 3 byte buffer, initialized to NUL
↳ bytes
>>> print sizeof(p), repr(p.raw)
3 '\x00\x00\x00'
>>> p = create_string_buffer("Hello") # create a buffer containing a NUL
↳ terminated string
>>> print sizeof(p), repr(p.raw)
6 'Hello\x00'
>>> print repr(p.value)
'Hello'
>>> p = create_string_buffer("Hello", 10) # create a 10 byte buffer
>>> print sizeof(p), repr(p.raw)
10 'Hello\x00\x00\x00\x00\x00'
>>> p.value = "Hi"
>>> print sizeof(p), repr(p.raw)
10 'Hi\x00lo\x00\x00\x00\x00\x00'
>>>
```

The `create_string_buffer()` function replaces the `c_buffer()` function (which is still available as an alias), as well as the `c_string()` function from earlier ctypes releases. To create a mutable memory block containing unicode characters of the C type `wchar_t` use the `create_unicode_buffer()` function.

Calling functions, continued

Note that `printf` prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```
>>> printf = libc.printf
>>> printf("Hello, %s\n", "World!")
Hello, World!
14
>>> printf("Hello, %S\n", u"World!")
Hello, World!
14
>>> printf("%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf("%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: Don't know how to convert parameter 2
>>>
```

As has been mentioned before, all Python types except integers, strings, and unicode strings have to be wrapped in their corresponding ctypes type, so that they can be converted to the required C data type:

```
>>> printf("An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

Calling functions with your own custom data types

You can also customize `ctypes` argument conversion to allow instances of your own classes be used as function arguments. `ctypes` looks for an `_as_parameter_` attribute and uses this as the function argument. Of course, it must be one of integer, string, or unicode:

```
>>> class Bottles(object):
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf("%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a `property()` which makes the data available.

Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute. `argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf("String '%s', Int %d, Double %f\n", "Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf("%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf("%s %d %f\n", "X", 2, 3)
X 2 3.000000
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C

function argument in this case. Again, the result should be an integer, string, unicode, a `ctypes` instance, or an object with an `_as_parameter_` attribute.

Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr("abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p    # c_char_p is a pointer to a string
>>> strchr("abcdef", ord("d"))
'def'
>>> print strchr("abcdef", ord("x"))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python string into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr("abcdef", "d")
'def'
>>> strchr("abcdef", "def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: one character string expected
>>> print strchr("abcdef", "x")
None
>>> strchr("abcdef", "d")
'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
```

(continues on next page)

(continued from previous page)

```
File "<stdin>", line 3, in ValidHandle
WindowsError: [Errno 126] The specified module could not be found.
>>>
```

`WinError` is a function which will call `Windows.FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the `byref()` function which is used to pass parameters by reference. The same effect can be achieved with the `pointer()` function, although `pointer()` does a lot more work since it constructs a real pointer object, so it is faster to use `byref()` if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer('\000' * 32)
>>> print i.value, f.value, repr(s.value)
0 0.0 ''
>>> libc.sscanf("1 3.14 Hello", "%d %f %s",
...             byref(i), byref(f), s)
3
>>> print i.value, f.value, repr(s.value)
1 3.1400001049 'Hello'
>>>
```

Structures and unions

Structures and unions must derive from the `Structure` and `Union` base classes which are defined in the `ctypes` module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of 2-tuples, containing a *field name* and a *field type*.

The field type must be a `ctypes` type like `c_int`, or any other derived `ctypes` type: structure, union, array, pointer.

Here is a simple example of a `POINT` structure, which contains two integers named `x` and `y`, and also shows how to initialize a structure in the constructor:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print point.x, point.y
10 20
>>> point = POINT(y=5)
>>> print point.x, point.y
0 5
```

(continues on next page)

(continued from previous page)

```
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a `RECT` structure which contains two `POINT`s named *upperleft* and *lowerright*:

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print rc.upperleft.x, rc.upperleft.y
0 5
>>> print rc.lowerright.x, rc.lowerright.y
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways:

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field *descriptors* can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```
>>> print POINT.x
<Field type=c_long, ofs=0, size=4>
>>> print POINT.y
<Field type=c_long, ofs=4, size=4>
>>>
```

Warning: `ctypes` does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

`ctypes` uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the `BigEndianStructure`, `LittleEndianStructure`, `BigEndianUnion`, and `LittleEndianUnion` base classes. These classes cannot contain pointer fields.

Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print Int.first_16
<Field type=c_long, ofs=0:0, bits=16>
>>> print Int.second_16
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print len(MyStruct().point_array)
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print pt.x, pt.y
```

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print ii
<c_long_Array_10 object at 0x...>
>>> for i in ii: print i,
...
1 2 3 4 5 6 7 8 9 10
>>>
```

Pointers

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another `c_int` instance to the pointer's `contents` attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print i
c_long(99)
>>> pi[0] = 22
>>> print i
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_int'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
```

(continues on next page)

(continued from previous page)

```

TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>

```

Calling the pointer type without an argument creates a NULL pointer. NULL pointers have a `False` boolean value:

```

>>> null_ptr = POINTER(c_int)()
>>> print bool(null_ptr)
False
>>>

```

`ctypes` checks for NULL when dereferencing pointers (but dereferencing invalid non-NULL pointers would crash Python):

```

>>> null_ptr[0]
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>

```

Type conversions

Usually, `ctypes` does strict type checking. This means, if you have `POINTER(c_int)` in the `argtypes` list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where `ctypes` accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, `ctypes` accepts an array of `c_int`:

```

>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print bar.values[i]
...
1
2
3
>>>

```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in `argtypes`, an object of the pointed type (`c_int` in this case) can be passed to the function. `ctypes` will apply the required *byref()* conversion in this case automatically.

To set a `POINTER` type field to NULL, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. `ctypes` provides a `cast()` function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or `c_int` arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the `cast()` function is handy.

The `cast()` function can be used to cast a `ctypes` instance into a pointer to a different `ctypes` data type. `cast()` takes two parameters, a `ctypes` object that is or can be converted to a pointer of some kind, and a `ctypes` pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, `cast()` can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print bar.values[0]
0
>>>
```

Incomplete Types

Incomplete Types are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into `ctypes` code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new class `cell` is not available in the class statement itself. In `ctypes`, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print p.name,
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>
```

Callback functions

`ctypes` allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function, the class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The `CFUNCTYPE` factory function creates types for callback functions using the normal `cdecl` calling convention, and, on Windows, the `WINFUNCTYPE` factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, this is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer else.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

For the first implementation of the callback function, we simply print the arguments we get, and return 0 (incremental development ;-):

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a, b
...     return 0
...
>>>
```

Create the C callable callback:

```
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

And we're ready to go:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
>>>
```

We know how to access the contents of a pointer, so lets redefine our callback:

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a[0], b[0]
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

Here is what we get on Windows:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 7 1
py_cmp_func 33 1
py_cmp_func 99 1
py_cmp_func 5 1
py_cmp_func 7 5
py_cmp_func 33 5
py_cmp_func 99 5
py_cmp_func 7 99
py_cmp_func 33 99
py_cmp_func 7 33
>>>
```

It is funny to see that on linux the sort function seems to work much more efficiently, it is doing less comparisons:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Ah, we're nearly done! The last step is to actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a[0], b[0]
...     return a[0] - b[0]
...
>>>
```

Final run on Windows:

```
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 33 7
py_cmp_func 99 33
py_cmp_func 5 99
py_cmp_func 1 99
py_cmp_func 33 7
py_cmp_func 1 33
py_cmp_func 5 33
py_cmp_func 5 7
py_cmp_func 1 7
py_cmp_func 5 1
>>>
```

and on Linux:

```
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

It is quite interesting to see that the Windows `qsort()` function needs more comparisons than the linux version!

As we can easily check, our array is sorted now:

```
>>> for i in ia: print i,
...
1 5 7 33 99
>>>
```

Note: Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), `ctypes` creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will *not* survive across different callbacks, even

when those calls are made from the same C thread.

Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api:

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print opt_flag
c_long(0)
>>>
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the Python docs: *This pointer is initialized to point to an array of “struct _frozen” records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.*

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with `ctypes`:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int)]
...
>>>
```

We have defined the struct `_frozen` data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "PyImport_FrozenModules")
>>>
```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the NULL entry:

```
>>> for item in table:
...     print item.name, item.size
...     if item.name is None:
...         break
...
__hello__ 104
__phello__ -104
__phello__.spam 104
None 0
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

Surprises

There are some edge cases in `ctypes` where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print rc.a.x, rc.a.y, rc.b.x, rc.b.y
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print rc.a.x, rc.a.y, rc.b.x, rc.b.y
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`'s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave different from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
'abc def ghi'
>>> s.value is s.value
False
>>>
```

Why is it printing `False`? `ctypes` instances are objects containing a memory block plus some *descriptors* accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the contents of the object is stored. Accessing the contents again constructs a new Python object each time!

Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing `ctypes` object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a `ValueError` is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print sizeof(short_array)
8
>>> resize(short_array, 4)
Traceback (most recent call last):
...
ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with `ctypes` is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

15.17.2 ctypes reference

Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler does (on platforms with several versions of a shared library the most recent should be loaded), while the `ctypes` library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like *.so*, *.dylib* or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (`/sbin/ldconfig`, `gcc`, and `objdump`) to find the library file. It returns the filename of the library file. Here are some examples:

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>
```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

```
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                  use_last_error=False)
```

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

```
class ctypes.OleDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                   use_last_error=False)
```

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific `HRESULT` code. `HRESULT` values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an `WindowsError` is automatically raised.

```
class ctypes.WinDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                   use_last_error=False)
```

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

On Windows CE only the standard calling convention is used, for convenience the `WinDLL` and `OleDLL` use the standard calling convention on this platform.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

```
class ctypes.PyDLL(name, mode=DEFAULT_MODE, handle=None)
```

Instances of this class behave like `CDLL` instances, except that the Python GIL is *not* released during the function

call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The `mode` parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage. On Windows, `mode` is ignored. On posix systems, `RTLD_NOW` is always added, and is not configurable.

The `use_errno` parameter, when set to true, enables a ctypes mechanism that allows accessing the system `errno` error number in a safe way. `ctypes` maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

New in version 2.6: The `use_last_error` and `use_errno` optional parameters were added.

`ctypes.RTLD_GLOBAL`

Flag to use as `mode` parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`

Flag to use as `mode` parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

`ctypes.DEFAULT_MODE`

The default mode which is used to load shared libraries. On OSX 10.3, this is `RTLD_GLOBAL`, otherwise it is the same as `RTLD_LOCAL`.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

`PyDLL._handle`

The system handle used to access the library.

`PyDLL._name`

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the `LibraryLoader` class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

class `ctypes.LibraryLoader` (*dlltype*)

Class which loads shared libraries. *dlltype* should be one of the `CDLL`, `PyDLL`, `WinDLL`, or `OleDLL` types.

`__getattr__()` has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

LoadLibrary (*name*)

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

`ctypes.cdll`

Creates *CDLL* instances.

`ctypes.windll`

Windows only: Creates *WinDLL* instances.

`ctypes.ole32`

Windows only: Creates *OleDLL* instances.

`ctypes.pydll`

Creates *PyDLL* instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

`ctypes.pythonapi`

An instance of *PyDLL* that exposes Python C API functions as attributes. Note that all these functions are assumed to return C `int`, which is of course not always the truth, so you have to assign the correct `restype` attribute to use these functions.

Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

class `ctypes._FuncPtr`

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

restype

Assign a ctypes type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as *restype* and assign a callable to the *errcheck* attribute.

argtypes

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the *argtypes* tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a *c_char_p* item in the *argtypes* tuple will convert a unicode string passed as argument into a byte string using ctypes conversion rules.

New: It is now possible to put items in `argtypes` which are not `ctypes` types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, `ctypes` instance). This allows defining adapters that can adapt custom objects as function parameters.

errcheck

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

callable (*result, func, arguments*)

result is what the foreign function returns, as specified by the `restype` attribute.

func is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

arguments is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

exception `ctypes.ArgumentError`

This exception is raised when a foreign function call cannot convert one of the passed arguments.

Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function.

`ctypes.CFUNCTYPE` (*restype, *argtypes, use_errno=False, use_last_error=False*)

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use_errno* is set to true, the `ctypes` private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; *use_last_error* does the same for the Windows error code.

Changed in version 2.6: The optional *use_errno* and *use_last_error* parameters were added.

`ctypes.WINFUNCTYPE` (*restype, *argtypes, use_errno=False, use_last_error=False*)

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where `WINFUNCTYPE()` is the same as `CFUNCTYPE()`. The function will release the GIL during the call. *use_errno* and *use_last_error* have the same meaning as above.

`ctypes.PYFUNCTYPE` (*restype, *argtypes*)

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

prototype (*address*)

Returns a foreign function at the specified address which must be an integer.

prototype (*callable*)

Create a C callable function (a callback function) from a Python *callable*.

prototype (*func_spec[, paramflags]*)

Returns a foreign function exported by a shared library. *func_spec* must be a 2-tuple (*name_or_ordinal, library*). The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

prototype (*vtbl_index*, *name*[, *paramflags*[, *iid*]])

Returns a foreign function that will call a COM method. *vtbl_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the *argtypes* tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

paramflags must be a tuple of the same length as *argtypes*.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

- 1 Specifies an input parameter to the function.
- 2 Output parameter. The foreign function fills in a value.
- 4 Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxA` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxA (
    HWND hWnd,
    LPCSTR lpText,
    LPCSTR lpCaption,
    UINT uType);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCSTR, LPCSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", None), (1, "flags",
→ 0)
>>> MessageBox = prototype(("MessageBoxA", windll.user32), paramflags)
>>>
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
>>>
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect (
```

(continues on next page)

(continued from previous page)

```
HWND hWnd,  
LPRECT lpRect);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError  
>>> from ctypes.wintypes import BOOL, HWND, RECT  
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))  
>>> paramflags = (1, "hwnd"), (2, "lprect")  
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)  
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the `GetWindowRect` function now returns a `RECT` instance, when called.

Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):  
...     if not result:  
...         raise WinError()  
...     return args  
...  
>>> GetWindowRect.errcheck = errcheck  
>>>
```

If the `errcheck` function returns the argument tuple it receives unchanged, *ctypes* continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```
>>> def errcheck(result, func, args):  
...     if not result:  
...         raise WinError()  
...     rc = args[1]  
...     return rc.left, rc.top, rc.bottom, rc.right  
...  
>>> GetWindowRect.errcheck = errcheck  
>>>
```

Utility functions

`ctypes.addressof(obj)`

Returns the address of the memory buffer as integer. *obj* must be an instance of a *ctypes* type.

`ctypes.alignment(obj_or_type)`

Returns the alignment requirements of a *ctypes* type. *obj_or_type* must be a *ctypes* type or instance.

`ctypes.byref(obj[, offset])`

Returns a light-weight pointer to *obj*, which must be an instance of a *ctypes* type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

New in version 2.6: The *offset* optional argument was added.

`ctypes.cast(obj, type)`

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(init_or_size[, size])`

This function creates a mutable character buffer. The returned object is a ctypes array of `c_char`.

init_or_size must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

If the first parameter is a unicode string, it is converted into an 8-bit string according to ctypes conversion rules.

`ctypes.create_unicode_buffer(init_or_size[, size])`

This function creates a mutable unicode character buffer. The returned object is a ctypes array of `c_wchar`.

init_or_size must be an integer which specifies the size of the array, or a unicode string which will be used to initialize the array items.

If a unicode string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

If the first parameter is an 8-bit string, it is converted into a unicode string according to ctypes conversion rules.

`ctypes.DllCanUnloadNow()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllCanUnloadNow` function that the `_ctypes` extension dll exports.

`ctypes.DllGetClassObject()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllGetClassObject` function that the `_ctypes` extension dll exports.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

Changed in version 2.6: Windows only: `find_library("m")` or `find_library("c")` return the result of a call to `find_msvcr()`.

`ctypes.util.find_msvcr()`

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

New in version 2.6.

`ctypes.FormatError([code])`

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

`ctypes.GetLastError()`

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

`ctypes.get_errno()`

Returns the current value of the ctypes-private copy of the system *errno* variable in the calling thread.

New in version 2.6.

`ctypes.get_last_error()`

Windows only: returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

New in version 2.6.

`ctypes.memmove(dst, src, count)`

Same as the standard C `memmove` library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

`ctypes.memset(dst, c, count)`

Same as the standard C `memset` library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

`ctypes.POINTER(type)`

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

`ctypes.pointer(obj)`

This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize(obj, size)`

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

`ctypes.set_conversion_mode(encoding, errors)`

This function sets the rules that ctypes objects use when converting between 8-bit strings and unicode strings. *encoding* must be a string specifying an encoding, like `'utf-8'` or `'mbcs'`, *errors* must be a string specifying the error handling on encoding/decoding errors. Examples of possible values are `"strict"`, `"replace"`, or `"ignore"`.

`set_conversion_mode()` returns a 2-tuple containing the previous conversion rules. On windows, the initial conversion rules are `('mbcs', 'ignore')`, on other systems `('ascii', 'strict')`.

`ctypes.set_errno(value)`

Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

New in version 2.6.

`ctypes.set_last_error(value)`

Windows only: set the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

New in version 2.6.

`ctypes.sizeof(obj_or_type)`

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

`ctypes.string_at(address[, size])`

This function returns the string starting at memory address *address*. If *size* is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

`ctypes.WinError(code=None, descr=None)`

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of `WindowsError`. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, `FormatError()` is called to get a textual description of the error.

`ctypes.wstring_at(address[, size])`

This function returns the wide character string starting at memory address *address* as unicode string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Data types

class `ctypes._CData`

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects`; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

from_buffer (*source*[, *offset*])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

New in version 2.6.

from_buffer_copy (*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

New in version 2.6.

from_address (*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

from_param (*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's `argtypes` tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

in_dll (*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

`_b_base_`

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The `_b_base_` read-only member is the root ctypes object that owns the memory block.

`_b_needsfree_`

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

`_objects`

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

Fundamental data types

`class ctypes._SimpleCData`

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. `_SimpleCData` is a subclass of `_CData`, so it inherits their methods and attributes.

Changed in version 2.6: ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

`value`

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character string, for character pointer types it is a Python string or unicode string.

When the `value` attribute is retrieved from a ctypes instance, usually a new object is returned each time. `ctypes` does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a `restype` of `c_char_p`, you will always receive a Python string, *not* a `c_char_p` instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of `c_void_p`, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

`class ctypes.c_byte`

Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

`class ctypes.c_char`

Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

`class ctypes.c_char_p`

Represents the C `char *` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a string.

`class ctypes.c_double`

Represents the C `double` datatype. The constructor accepts an optional float initializer.

class `ctypes.c_longdouble`

Represents the C long double datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

New in version 2.6.

class `ctypes.c_float`

Represents the C float datatype. The constructor accepts an optional float initializer.

class `ctypes.c_int`

Represents the C signed int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

class `ctypes.c_int8`

Represents the C 8-bit signed int datatype. Usually an alias for `c_byte`.

class `ctypes.c_int16`

Represents the C 16-bit signed int datatype. Usually an alias for `c_short`.

class `ctypes.c_int32`

Represents the C 32-bit signed int datatype. Usually an alias for `c_int`.

class `ctypes.c_int64`

Represents the C 64-bit signed int datatype. Usually an alias for `c_longlong`.

class `ctypes.c_long`

Represents the C signed long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_longlong`

Represents the C signed long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_short`

Represents the C signed short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_size_t`

Represents the C size_t datatype.

class `ctypes.c_ssize_t`

Represents the C ssize_t datatype.

New in version 2.7.

class `ctypes.c_ubyte`

Represents the C unsigned char datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_uint`

Represents the C unsigned int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for `c_ulong`.

class `ctypes.c_uint8`

Represents the C 8-bit unsigned int datatype. Usually an alias for `c_ubyte`.

class `ctypes.c_uint16`

Represents the C 16-bit unsigned int datatype. Usually an alias for `c_ushort`.

class `ctypes.c_uint32`

Represents the C 32-bit unsigned int datatype. Usually an alias for `c_uint`.

class `ctypes.c_uint64`

Represents the C 64-bit unsigned int datatype. Usually an alias for `c_ulonglong`.

class `ctypes.c_ulong`

Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_ulonglong`

Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_ushort`

Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_void_p`

Represents the C void * type. The value is represented as integer. The constructor accepts an optional integer initializer.

class `ctypes.c_wchar`

Represents the C wchar_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class `ctypes.c_wchar_p`

Represents the C wchar_t * datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class `ctypes.c_bool`

Represent the C bool datatype (more accurately, _Bool from C99). Its value can be True or False, and the constructor accepts any object that has a truth value.

New in version 2.6.

class `ctypes.HRESULT`

Windows only: Represents a HRESULT value, which contains success or error information for a function or method call.

class `ctypes.py_object`

Represents the C PyObject * datatype. Calling this without an argument creates a NULL PyObject * pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

Structured data types

class `ctypes.Union(*args, **kw)`

Abstract base class for unions in native byte order.

class `ctypes.BigEndianStructure(*args, **kw)`

Abstract base class for structures in *big endian* byte order.

class `ctypes.LittleEndianStructure(*args, **kw)`

Abstract base class for structures in *little endian* byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class `ctypes.Structure(*args, **kw)`

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `__fields__` class variable. `ctypes` will create *descriptors* which allow reading and writing the fields by direct attribute accesses. These are the

`__fields__`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `__fields__` class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List.__fields__ = [("pNext", POINTER(List)),
                  ...
                  ]
```

The `__fields__` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `__fields__` class variable will raise an `AttributeError`.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the `__fields__` defined in the sub-subclass, if any.

`__pack__`

An optional small integer that allows overriding the alignment of structure fields in the instance. `__pack__` must already be defined when `__fields__` is assigned, otherwise it will have no effect.

`__anonymous__`

An optional sequence that lists the names of unnamed (anonymous) fields. `__anonymous__` must be already defined when `__fields__` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allow accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    __fields__ = [("lptdesc", POINTER(TYPEDESC)),
                  ("lpadesc", POINTER(ARRAYDESC)),
                  ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    __anonymous__ = ("u",)
    __fields__ = [("u", _U),
                  ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the `TYPEDESC` instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `__fields__` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in `__fields__`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `__fields__` with the same name, or create new attributes for names not present in `__fields__`.

Arrays and pointers

class `ctypes.Array(*args)`

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any `ctypes` data type with a positive integer. Alternatively, you can subclass this type and define `__length__` and `__type__` class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an `Array`.

__length__

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an `IndexError`. Will be returned by `len()`.

__type__

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class `ctypes._Pointer`

Private, abstract base class for pointers.

Concrete pointer types are created by calling `POINTER()` with the type that will be pointed to; this is done automatically by `pointer()`.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so `len()` will raise `TypeError`. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

__type__

Specifies the type pointed to.

contents

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

OPTIONAL OPERATING SYSTEM SERVICES

The modules described in this chapter provide interfaces to operating system features that are available on selected operating systems only. The interfaces are generally modeled after the Unix or C interfaces but they are available on some other systems as well (e.g. Windows or NT). Here's an overview:

16.1 `select` — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

The module defines the following:

exception `select.error`

The exception raised when an error occurs. The accompanying value is a pair containing the numeric error code from `errno` and the corresponding string, as would be printed by the C function `perror()`.

`select.epoll([sizehint=-1])`

(Only supported on Linux 2.5.44 and newer.) Returns an edge polling object, which can be used as Edge or Level Triggered interface for I/O events; see section *Edge and Level Trigger Polling (epoll) Objects* below for the methods supported by epolling objects.

New in version 2.6.

`select.poll()`

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section *Polling Objects* below for the methods supported by polling objects.

`select.kqueue()`

(Only supported on BSD.) Returns a kernel queue object; see section *Kqueue Objects* below for the methods supported by kqueue objects.

New in version 2.6.

`select.kevent(ident, filter=KQ_FILTER_READ, flags=KQ_EV_ADD, fflags=0, data=0, udata=0)`

(Only supported on BSD.) Returns a kernel event object; see section *Kevent Objects* below for the methods supported by kevent objects.

New in version 2.6.

`select.select(rlist, wlist, xlist[, timeout])`

This is a straightforward interface to the Unix `select()` system call. The first three arguments are sequences

of ‘waitable objects’: either integers representing file descriptors or objects with a parameterless method named `fileno()` returning such an integer:

- *rlist*: wait until ready for reading
- *wlist*: wait until ready for writing
- *xlist*: wait for an “exceptional condition” (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional *timeout* argument specifies a time-out as a floating point number in seconds. When the *timeout* argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python file objects (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a *wrapper* class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

Note: File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.

`select.PIPE_BUF`

Files reported as ready for writing by `select()`, `poll()` or similar interfaces in this module are guaranteed to not block on a write of up to `PIPE_BUF` bytes. This value is guaranteed by POSIX to be at least 512. Availability: Unix.

New in version 2.7.

16.1.1 Edge and Level Trigger Polling (epoll) Objects

<http://linux.die.net/man/4/epoll>

eventmask

| Constant | Meaning |
|--------------|---|
| EPOLLIN | Available for read |
| EPOLLOUT | Available for write |
| EPOLLPRI | Urgent data for read |
| EPOLLERR | Error condition happened on the assoc. fd |
| EPOLLHUP | Hang up happened on the assoc. fd |
| EPOLLET | Set Edge Trigger behavior, the default is Level Trigger behavior |
| EPOLLONESHOT | Set one-shot behavior. After one event is pulled out, the fd is internally disabled |
| EPOLLRDNORM | Equivalent to EPOLLIN |
| EPOLLRDBAND | Priority data band can be read. |
| EPOLLWRNORM | Equivalent to EPOLLOUT |
| EPOLLWRBAND | Priority data may be written. |
| EPOLLMG | Ignored. |

`epoll.close()`

Close the control file descriptor of the epoll object.

`epoll.fileno()`
Return the file descriptor number of the control fd.

`epoll.fromfd(fd)`
Create an epoll object from a given file descriptor.

`epoll.register(fd[, eventmask])`
Register a fd descriptor with the epoll object.

Note: Registering a file descriptor that's already registered raises an `IOError` – contrary to *Polling Objects's* `register`.

`epoll.modify(fd, eventmask)`
Modify a register file descriptor.

`epoll.unregister(fd)`
Remove a registered file descriptor from the epoll object.

`epoll.poll([timeout=-1[, maxevents=-1]])`
Wait for events. timeout in seconds (float)

16.1.2 Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is $O(\text{highest file descriptor})$, while `poll()` is $O(\text{number of file descriptors})$.

`poll.register(fd[, eventmask])`
Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

| Constant | Meaning |
|-----------------------|--|
| <code>POLLIN</code> | There is data to read |
| <code>POLLPRI</code> | There is urgent data to read |
| <code>POLLOUT</code> | Ready for output: writing will not block |
| <code>POLLERR</code> | Error condition of some sort |
| <code>POLLHUP</code> | Hung up |
| <code>POLLNVAL</code> | Invalid request: descriptor not open |

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

`poll.modify(fd, eventmask)`
Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an `IOError` exception with `errno.ENOENT` to be raised.

New in version 2.6.

`poll.unregister(fd)`
Remove a file descriptor being tracked by a polling object. Just like the `register()` method, `fd` can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a `KeyError` exception to be raised.

`poll.poll([timeout])`

Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. `fd` is the file descriptor, and `event` is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If `timeout` is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If `timeout` is omitted, negative, or `None`, the call will block until there is an event for this poll object.

16.1.3 Kqueue Objects

`kqueue.close()`

Close the control file descriptor of the kqueue object.

`kqueue.fileno()`

Return the file descriptor number of the control fd.

`kqueue.fromfd(fd)`

Create a kqueue object from a given file descriptor.

`kqueue.control(changelist, max_events[, timeout=None])` → eventlist

Low level interface to kevent

- `changelist` must be an iterable of kevent object or `None`
- `max_events` must be 0 or a positive integer
- `timeout` in seconds (floats possible)

16.1.4 Kevent Objects

<https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2>

`kevent.ident`

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor `ident` can either be an int or an object with a `fileno()` function. `kevent` stores the integer internally.

`kevent.filter`

Name of the kernel filter.

| Constant | Meaning |
|-------------------------------|---|
| <code>KQ_FILTER_READ</code> | Takes a descriptor and returns whenever there is data available to read |
| <code>KQ_FILTER_WRITE</code> | Takes a descriptor and returns whenever there is data available to write |
| <code>KQ_FILTER_AIO</code> | AIO requests |
| <code>KQ_FILTER_VNODE</code> | Returns when one or more of the requested events watched in <code>fflag</code> occurs |
| <code>KQ_FILTER_PROC</code> | Watch for events on a process id |
| <code>KQ_FILTER_NETDEV</code> | Watch for events on a network device [not available on Mac OS X] |
| <code>KQ_FILTER_SIGNAL</code> | Returns whenever the watched signal is delivered to the process |
| <code>KQ_FILTER_TIMER</code> | Establishes an arbitrary timer |

`kevent.flags`

Filter action.

| Constant | Meaning |
|----------------|--|
| KQ_EV_ADD | Adds or modifies an event |
| KQ_EV_DELETE | Removes an event from the queue |
| KQ_EV_ENABLE | Permits <code>control()</code> to return the event |
| KQ_EV_DISABLE | Disable event |
| KQ_EV_ONESHOT | Removes event after first occurrence |
| KQ_EV_CLEAR | Reset the state after an event is retrieved |
| KQ_EV_SYSFLAGS | internal event |
| KQ_EV_FLAG1 | internal event |
| KQ_EV_EOF | Filter specific EOF condition |
| KQ_EV_ERROR | See return values |

`kevent.fflags`

Filter specific flags.

KQ_FILTER_READ and KQ_FILTER_WRITE filter flags:

| Constant | Meaning |
|---------------|-----------------------------------|
| KQ_NOTE_LOWAT | low water mark of a socket buffer |

KQ_FILTER_VNODE filter flags:

| Constant | Meaning |
|----------------|--------------------------------|
| KQ_NOTE_DELETE | <i>unlink()</i> was called |
| KQ_NOTE_WRITE | a write occurred |
| KQ_NOTE_EXTEND | the file was extended |
| KQ_NOTE_ATTRIB | an attribute was changed |
| KQ_NOTE_LINK | the link count has changed |
| KQ_NOTE_RENAME | the file was renamed |
| KQ_NOTE_REVOKE | access to the file was revoked |

KQ_FILTER_PROC filter flags:

| Constant | Meaning |
|-------------------|---|
| KQ_NOTE_EXIT | the process has exited |
| KQ_NOTE_FORK | the process has called <i>fork()</i> |
| KQ_NOTE_EXEC | the process has executed a new process |
| KQ_NOTE_PCTRLMASK | internal filter flag |
| KQ_NOTE_PDATAMASK | internal filter flag |
| KQ_NOTE_TRACK | follow a process across <i>fork()</i> |
| KQ_NOTE_CHILD | returned on the child process for <i>NOTE_TRACK</i> |
| KQ_NOTE_TRACKERR | unable to attach to a child |

KQ_FILTER_NETDEV filter flags (not available on Mac OS X):

| Constant | Meaning |
|------------------|-----------------------|
| KQ_NOTE_LINKUP | link is up |
| KQ_NOTE_LINKDOWN | link is down |
| KQ_NOTE_LINKINV | link state is invalid |

`kevent.data`
Filter specific data.

`kevent.udata`
User defined value.

16.2 threading — Higher-level threading interface

Source code: [Lib/threading.py](#)

This module constructs higher-level threading interfaces on top of the lower level *thread* module. See also the *mutex* and *Queue* modules.

The *dummy_threading* module is provided for situations where *threading* cannot be used because *thread* is missing.

Note: Starting with Python 2.6, this module provides **PEP 8** compliant aliases and properties to replace the `camelCase` names that were inspired by Java's threading API. This updated API is compatible with that of the *multiprocessing* module. However, no schedule has been set for the deprecation of the `camelCase` names and they remain fully supported in both Python 2.x and 3.x.

Note: Starting with Python 2.5, several Thread methods raise *RuntimeError* instead of *AssertionError* if called erroneously.

CPython implementation detail: In CPython, due to the *Global Interpreter Lock*, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use *multiprocessing*. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

This module defines the following functions and objects:

`threading.active_count()`

`threading.activeCount()`

Return the number of *Thread* objects currently alive. The returned count is equal to the length of the list returned by *enumerate()*.

Changed in version 2.6: Added `active_count()` spelling.

`threading.Condition()`

A factory function that returns a new condition variable object. A condition variable allows one or more threads to wait until they are notified by another thread.

See *Condition Objects*.

`threading.current_thread()`

`threading.currentThread()`

Return the current *Thread* object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the *threading* module, a dummy thread object with limited functionality is returned.

Changed in version 2.6: Added `current_thread()` spelling.

`threading.enumerate()`

Return a list of all *Thread* objects currently alive. The list includes daemon threads, dummy thread objects created by `current_thread()`, and the main thread. It excludes terminated threads and threads that have not yet been started.

`threading.Event()`

A factory function that returns a new event object. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

See *Event Objects*.

class `threading.local`

A class that represents thread-local data. Thread-local data are data whose values are thread specific. To manage thread-local data, just create an instance of *local* (or a subclass) and store attributes on it:

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

For more details and extensive examples, see the documentation string of the `_threading_local` module.

New in version 2.4.

`threading.Lock()`

A factory function that returns a new primitive lock object. Once a thread has acquired it, subsequent attempts to acquire it block, until it is released; any thread may release it.

See *Lock Objects*.

`threading.RLock()`

A factory function that returns a new reentrant lock object. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

See *RLock Objects*.

`threading.Semaphore([value])`

A factory function that returns a new semaphore object. A semaphore manages a counter representing the number of `release()` calls minus the number of `acquire()` calls, plus an initial value. The `acquire()` method blocks if necessary until it can return without making the counter negative. If not given, *value* defaults to 1.

See *Semaphore Objects*.

`threading.BoundedSemaphore([value])`

A factory function that returns a new bounded semaphore object. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, *ValueError* is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

class `threading.Thread`

A class that represents a thread of control. This class can be safely subclassed in a limited fashion.

See *Thread Objects*.

class `threading.Timer`

A thread that executes a function after a specified interval has passed.

See *Timer Objects*.

`threading.settrace(func)`

Set a trace function for all threads started from the *threading* module. The *func* will be passed to `sys.settrace()` for each thread, before its `run()` method is called.

New in version 2.3.

`threading.setprofile(func)`

Set a profile function for all threads started from the `threading` module. The *func* will be passed to `sys.setprofile()` for each thread, before its `run()` method is called.

New in version 2.3.

`threading.stack_size([size])`

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a `ThreadError` is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

New in version 2.5.

exception `threading.ThreadError`

Raised for various threading-related errors as described below. Note that many interfaces use `RuntimeError` instead of `ThreadError`.

Detailed interfaces for the objects are documented below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's `Thread` class supports a subset of the behavior of Java's `Thread` class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's `Thread` class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

16.2.1 Thread Objects

This class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and `run()` methods of this class.

Once a thread object is created, its activity must be started by calling the thread's `start()` method. This invokes the `run()` method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its `run()` method terminates – either normally, or by raising an unhandled exception. The `is_alive()` method tests whether the thread is alive.

Other threads can call a thread's `join()` method. This blocks the calling thread until the thread whose `join()` method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the `name` attribute.

A thread can be flagged as a "daemon thread". The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the `daemon` property.

Note: Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an *Event*.

There is a “main thread” object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that “dummy thread objects” are created. These are thread objects corresponding to “alien threads”, which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be `join()`ed. They are never deleted, since it is impossible to detect the termination of alien threads.

class `threading.Thread` (*group=None, target=None, name=None, args=(), kwargs={}*)

This constructor should always be called with keyword arguments. Arguments are:

group should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

target is the callable object to be invoked by the `run()` method. Defaults to `None`, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form “Thread-*N*” where *N* is a small decimal number.

args is the argument tuple for the target invocation. Defaults to `()`.

kwargs is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

start()

Start the thread’s activity.

It must be called at most once per thread object. It arranges for the object’s `run()` method to be invoked in a separate thread of control.

This method will raise a `RuntimeError` if called more than once on the same thread object.

run()

Method representing the thread’s activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object’s constructor as the *target* argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

join([*timeout*])

Wait until the thread terminates. This blocks the calling thread until the thread whose `join()` method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As `join()` always returns `None`, you must call `isAlive()` after `join()` to decide whether a timeout happened – if the thread is still alive, the `join()` call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be `join()`ed many times.

`join()` raises a `RuntimeError` if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to `join()` a thread before it has been started and attempts to do so raises the same exception.

name

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

New in version 2.6.

getName()**setName()**

Pre-2.6 API for *name*.

ident

The ‘thread identifier’ of this thread or `None` if the thread has not been started. This is a nonzero integer. See the `thread.getIdent()` function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

New in version 2.6.

is_alive()**isAlive()**

Return whether the thread is alive.

This method returns `True` just before the `run()` method starts until just after the `run()` method terminates. The module function `enumerate()` returns a list of all alive threads.

Changed in version 2.6: Added `is_alive()` spelling.

daemon

A boolean value indicating whether this thread is a daemon thread (`True`) or not (`False`). This must be set before `start()` is called, otherwise `RuntimeError` is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to `daemon = False`.

The entire Python program exits when no alive non-daemon threads are left.

New in version 2.6.

isDaemon()**setDaemon()**

Pre-2.6 API for *daemon*.

16.2.2 Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the `thread` extension module.

A primitive lock is in one of two states, “locked” or “unlocked”. It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another thread changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `ThreadError` will be raised.

When more than one thread is blocked in `acquire()` waiting for the state to turn to unlocked, only one thread proceeds when a `release()` call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

`Lock.acquire([blocking])`

Acquire a lock, blocking or non-blocking.

When invoked with the *blocking* argument set to `True` (the default), block until the lock is unlocked, then set it to locked and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call with *blocking* set to `True` would block, return `False` immediately; otherwise, set the lock to locked and return `True`.

`Lock.release()`

Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `ThreadError` is raised.

There is no return value.

16.2.3 RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of “owning thread” and “recursion level” in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its `acquire()` method; this returns once the thread owns the lock. To unlock the lock, a thread calls its `release()` method. `acquire()/release()` call pairs may be nested; only the final `release()` (the `release()` of the outermost pair) resets the lock to unlocked and allows another thread blocked in `acquire()` to proceed.

`RLock.acquire([blocking=1])`

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the *blocking* argument set to `true`, do the same thing as when called without arguments, and return `true`.

When invoked with the *blocking* argument set to `false`, do not block. If a call without an argument would block, return `false` immediately; otherwise, do the same thing as when called without arguments, and return `true`.

`RLock.release()`

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A `RuntimeError` is raised if this method is called when the lock is unlocked.

There is no return value.

16.2.4 Condition Objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. (Passing one in is useful when several condition variables must share the same lock.)

A condition variable has `acquire()` and `release()` methods that call the corresponding methods of the associated lock. It also has a `wait()` method, and `notify()` and `notifyAll()` methods. These three must only be called when the calling thread has acquired the lock, otherwise a `RuntimeError` is raised.

The `wait()` method releases the lock, and then blocks until it is awakened by a `notify()` or `notifyAll()` call for the same condition variable in another thread. Once awakened, it re-acquires the lock and returns. It is also possible to specify a timeout.

The `notify()` method wakes up one of the threads waiting for the condition variable, if any are waiting. The `notifyAll()` method wakes up all threads waiting for the condition variable.

Note: the `notify()` and `notifyAll()` methods don't release the lock; this means that the thread or threads awakened will not return from their `wait()` call immediately, but only when the thread that called `notify()` or `notifyAll()` finally relinquishes ownership of the lock.

Tip: the typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call `wait()` repeatedly until they see the desired state, while threads that modify the state call `notify()` or `notifyAll()` when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

```
# Consume one item
cv.acquire()
while not an_item_is_available():
    cv.wait()
get_an_available_item()
cv.release()

# Produce one item
cv.acquire()
make_an_item_available()
cv.notify()
cv.release()
```

To choose between `notify()` and `notifyAll()`, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

class `threading.Condition([lock])`

If the `lock` argument is given and not `None`, it must be a `Lock` or `RLock` object, and it is used as the underlying lock. Otherwise, a new `RLock` object is created and used as the underlying lock.

acquire (*args)

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

release ()

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

wait ([timeout])

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notifyAll()` call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the `timeout` argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an `RLock`, it is not released using its `release()` method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the `RLock` class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

`notify(n=1)`

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method wakes up at most *n* of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly *n* threads, if at least *n* threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than *n* threads.

Note: an awakened thread does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

`notify_all()`

`notifyAll()`

Wake up all threads waiting on this condition. This method acts like `notify()`, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

Changed in version 2.6: Added `notify_all()` spelling.

16.2.5 Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used `P()` and `V()` instead of `acquire()` and `release()`).

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some other thread calls `release()`.

`class threading.Semaphore([value])`

The optional argument gives the initial *value* for the internal counter; it defaults to 1. If the *value* given is less than 0, `ValueError` is raised.

`acquire([blocking])`

Acquire a semaphore.

When invoked without arguments: if the internal counter is larger than zero on entry, decrement it by one and return immediately. If it is zero on entry, block, waiting until some other thread has called `release()` to make it larger than zero. This is done with proper interlocking so that if multiple `acquire()` calls are blocked, `release()` will wake exactly one of them up. The implementation may pick one at random, so the order in which blocked threads are awakened should not be relied on. There is no return value in this case.

When invoked with *blocking* set to true, do the same thing as when called without arguments, and return true.

When invoked with *blocking* set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

`release()`

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another thread is waiting for it to become larger than zero again, wake up that thread.

Semaphore Example

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```
maxconnections = 5
...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's `acquire` and `release` methods when they need to connect to the server:

```
pool_sema.acquire()
conn = connectdb()
... use connection ...
conn.close()
pool_sema.release()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

16.2.6 Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

class `threading.Event`

The internal flag is initially false.

is_set()

isSet()

Return true if and only if the internal flag is true.

Changed in version 2.6: Added `is_set()` spelling.

set()

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call `wait()` once the flag is true will not block at all.

clear()

Reset the internal flag to false. Subsequently, threads calling `wait()` will block until `set()` is called to set the internal flag to true again.

wait([*timeout*])

Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls `set()` to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns the internal flag on exit, so it will always return `True` except if a timeout is given and the operation times out.

Changed in version 2.7: Previously, the method always returned `None`.

16.2.7 Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. `Timer` is a subclass of `Thread` and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their `start()` method. The timer can be stopped (before its action has begun) by calling the `cancel()` method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```
def hello():
    print "hello, world"

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be printed
```

class `threading.Timer` (*interval*, *function*, *args*=[], *kwargs*={})

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed.

cancel ()

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

16.2.8 Using locks, conditions, and semaphores in the with statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited.

Currently, `Lock`, `RLock`, `Condition`, `Semaphore`, and `BoundedSemaphore` objects may be used as `with` statement context managers. For example:

```
import threading

some_rlock = threading.RLock()

with some_rlock:
    print "some_rlock is locked while this executes"
```

16.2.9 Importing in threaded code

While the import machinery is thread-safe, there are two key restrictions on threaded imports due to inherent limitations in the way that thread-safety is provided:

- Firstly, other than in the main module, an import should not have the side effect of spawning a new thread and then waiting for that thread in any way. Failing to abide by this restriction can lead to a deadlock if the spawned thread directly or indirectly attempts to import a module.
- Secondly, all import attempts must be completed before the interpreter starts shutting itself down. This can be most easily achieved by only performing imports from non-daemon threads created through the `threading` module. Daemon threads and threads created directly with the `thread` module will require some other form of synchronization to ensure they do not attempt imports after system shutdown has commenced. Failure to abide by this restriction will lead to intermittent exceptions and crashes during interpreter shutdown (as the late imports attempt to access machinery which is no longer in a valid state).

16.3 thread — Multiple threads of control

Note: The `thread` module has been renamed to `_thread` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3; however, you should consider using the high-level `threading` module instead.

This module provides low-level primitives for working with multiple threads (also called *light-weight processes* or *tasks*) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called *mutexes* or *binary semaphores*) are provided. The `threading` module provides an easier to use and higher-level threading API built on top of this module.

The module is optional. It is supported on Windows, Linux, SGI IRIX, Solaris 2.x, as well as on systems that have a POSIX thread (a.k.a. “pthread”) implementation. For systems lacking the `thread` module, the `dummy_thread` module is available. It duplicates this module’s interface and can be used as a drop-in replacement.

It defines the following constant and functions:

exception `thread.error`

Raised on thread-specific errors.

`thread.LockType`

This is the type of lock objects.

`thread.start_new_thread(function, args[, kwargs])`

Start a new thread and return its identifier. The thread executes the function *function* with the argument list *args* (which must be a tuple). The optional *kwargs* argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with an unhandled exception, a stack trace is printed and then the thread exits (but other threads continue to run).

`thread.interrupt_main()`

Raise a `KeyboardInterrupt` exception in the main thread. A subthread can use this function to interrupt the main thread.

New in version 2.3.

`thread.exit()`

Raise the `SystemExit` exception. When not caught, this will cause the thread to exit silently.

`thread.allocate_lock()`

Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

`thread.get_ident()`

Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

`thread.stack_size([size])`

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32kB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, the `error` exception is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

New in version 2.5.

Lock objects have the following methods:

`lock.acquire([waitflag])`

Without the optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that's their reason for existence). If the integer *waitflag* argument is present, the action depends on its value: if it is zero, the lock is only acquired if it can be acquired immediately without waiting, while if it is nonzero, the lock is acquired unconditionally as before. The return value is `True` if the lock is acquired successfully, `False` if not.

`lock.release()`

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

`lock.locked()`

Return the status of the lock: `True` if it has been acquired by some thread, `False` if not.

In addition to these methods, lock objects can also be used via the `with` statement, e.g.:

```
import thread

a_lock = thread.allocate_lock()

with a_lock:
    print "a_lock is locked while this executes"
```

Caveats:

- Threads interact strangely with interrupts: the *KeyboardInterrupt* exception will be received by an arbitrary thread. (When the *signal* module is available, interrupts always go to the main thread.)
- Calling `sys.exit()` or raising the *SystemExit* exception is equivalent to calling `thread.exit()`.
- It is not possible to interrupt the `acquire()` method on a lock — the *KeyboardInterrupt* exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On SGI IRIX using the native thread implementation, they survive. On most other systems, they are killed without executing `try ... finally` clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and the standard I/O files are not flushed.

16.4 dummy_threading — Drop-in replacement for the threading module

Source code: [Lib/dummy_threading.py](#)

This module provides a duplicate interface to the *threading* module. It is meant to be imported when the *thread* module is not provided on a platform.

Suggested usage is:

```
try:
    import threading as _threading
except ImportError:
    import dummy_threading as _threading
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

16.5 `dummy_thread` — Drop-in replacement for the `thread` module

Note: The `dummy_thread` module has been renamed to `_dummy_thread` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3; however, you should consider using the high-level `dummy_threading` module instead.

Source code: [Lib/dummy_thread.py](#)

This module provides a duplicate interface to the `thread` module. It is meant to be imported when the `thread` module is not provided on a platform.

Suggested usage is:

```
try:
    import thread as _thread
except ImportError:
    import dummy_thread as _thread
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

16.6 `multiprocessing` — Process-based “threading” interface

New in version 2.6.

16.6.1 Introduction

`multiprocessing` is a package that supports spawning processes using an API similar to the `threading` module. The `multiprocessing` package offers both local and remote concurrency, effectively side-stepping the *Global Interpreter Lock* by using subprocesses instead of threads. Due to this, the `multiprocessing` module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The `multiprocessing` module also introduces APIs which do not have analogs in the `threading` module. A prime example of this is the `Pool` object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using `Pool`,

```

from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    p = Pool(5)
    print(p.map(f, [1, 2, 3]))

```

will print to standard output

```
[1, 4, 9]
```

The Process class

In *multiprocessing*, processes are spawned by creating a *Process* object and then calling its *start()* method. *Process* follows the API of *threading.Thread*. A trivial example of a multiprocess program is

```

from multiprocessing import Process

def f(name):
    print 'hello', name

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()

```

To show the individual process IDs involved, here is an expanded example:

```

from multiprocessing import Process
import os

def info(title):
    print title
    print 'module name:', __name__
    if hasattr(os, 'getppid'): # only available on Unix
        print 'parent process:', os.getppid()
    print 'process id:', os.getpid()

def f(name):
    info('function f')
    print 'hello', name

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()

```

For an explanation of why (on Windows) the `if __name__ == '__main__':` part is necessary, see *Programming guidelines*.

Exchanging objects between processes

multiprocessing supports two types of communication channel between processes:

Queues

The *Queue* class is a near clone of *Queue.Queue*. For example:

```
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print q.get()      # prints "[42, None, 'hello']"
    p.join()
```

Queues are thread and process safe.

Pipes

The *Pipe()* function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print parent_conn.recv()  # prints "[42, None, 'hello']"
    p.join()
```

The two connection objects returned by *Pipe()* represent the two ends of the pipe. Each connection object has *send()* and *recv()* methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

Synchronization between processes

multiprocessing contains equivalents of all the synchronization primitives from *threading*. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    print 'hello world', i
    l.release()
```

(continues on next page)

(continued from previous page)

```

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()

```

Without using the lock output from the different processes is liable to get all mixed up.

Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then *multiprocessing* provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using *Value* or *Array*. For example, the following code

```

from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print num.value
    print arr[:]

```

will print

```

3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]

```

The 'd' and 'i' arguments used when creating *num* and *arr* are typecodes of the kind used by the *array* module: 'd' indicates a double precision float and 'i' indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the *multiprocessing.sharedctypes* module which supports the creation of arbitrary ctypes objects allocated from shared memory.

Server process

A manager object returned by *Manager()* controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by *Manager()* will support types *list*, *dict*, *Namespace*, *Lock*, *RLock*, *Semaphore*, *BoundedSemaphore*, *Condition*, *Event*, *Queue*, *Value* and *Array*. For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    manager = Manager()

    d = manager.dict()
    l = manager.list(range(10))

    p = Process(target=f, args=(d, l))
    p.start()
    p.join()

    print d
    print l
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

Using a pool of workers

The `Pool` class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    pool = Pool(processes=4)           # start 4 worker processes

    # print "[0, 1, 4, ..., 81]"
    print pool.map(f, range(10))

    # print same numbers in arbitrary order
    for i in pool.imap_unordered(f, range(10)):
        print i

    # evaluate "f(20)" asynchronously
    res = pool.apply_async(f, (20,))  # runs in *only* one process
```

(continues on next page)

(continued from previous page)

```

print res.get(timeout=1)                # prints "400"

# evaluate "os.getpid()" asynchronously
res = pool.apply_async(os.getpid, ()) # runs in *only* one process
print res.get(timeout=1)                # prints the PID of that process

# launching multiple evaluations asynchronously *may* use more processes
multiple_results = [pool.apply_async(os.getpid, ()) for i in range(4)]
print [res.get(timeout=1) for res in multiple_results]

# make a single worker sleep for 10 secs
res = pool.apply_async(time.sleep, (10,))
try:
    print res.get(timeout=1)
except TimeoutError:
    print "We lacked patience and got a multiprocessing.TimeoutError"

```

Note that the methods of a pool should only ever be used by the process which created it.

Note: Functionality within this package requires that the `__main__` module be importable by the children. This is covered in *Programming guidelines* however it is worth pointing out here. This means that some examples, such as the Pool examples will not work in the interactive interpreter. For example:

```

>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'

```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the master process somehow.)

16.6.2 Reference

The *multiprocessing* package mostly replicates the API of the *threading* module.

Process and exceptions

class multiprocessing.**Process** (*group=None, target=None, name=None, args=(), kwargs={}*)

Process objects represent activity that is run in a separate process. The *Process* class has equivalents of all the methods of *threading.Thread*.

The constructor should always be called with keyword arguments. *group* should always be *None*; it exists solely for compatibility with *threading.Thread*. *target* is the callable object to be invoked by the *run()* method. It defaults to *None*, meaning nothing is called. *name* is the process name. By default, a unique name is constructed

of the form 'Process- $N_1:N_2:\dots:N_k$ ' where N_1, N_2, \dots, N_k is a sequence of integers whose length is determined by the *generation* of the process. *args* is the argument tuple for the target invocation. *kwargs* is a dictionary of keyword arguments for the target invocation. By default, no arguments are passed to *target*.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (`Process.__init__()`) before doing anything else to the process.

run()

Method representing the process's activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

start()

Start the process's activity.

This must be called at most once per process object. It arranges for the object's `run()` method to be invoked in a separate process.

join([*timeout*])

Block the calling thread until the process whose `join()` method is called terminates or until the optional timeout occurs.

If *timeout* is `None` then there is no timeout.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

name

The process's name.

The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name. The initial name is set by the constructor.

is_alive()

Return whether the process is alive.

Roughly, a process object is alive from the moment the `start()` method returns until the child process terminates.

daemon

The process's daemon flag, a Boolean value. This must be set before `start()` is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemon child processes.

Note that a daemon process is not allowed to create child processes. Otherwise a daemon process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemon processes have exited.

In addition to the `threading.Thread` API, `Process` objects also support the following attributes and methods:

pid

Return the process ID. Before the process is spawned, this will be `None`.

exitcode

The child's exit code. This will be `None` if the process has not yet terminated. A negative value $-N$ indicates that the child was terminated by signal N .

authkey

The process's authentication key (a byte string).

When *multiprocessing* is initialized the main process is assigned a random string using *os.urandom()*.

When a *Process* object is created, it will inherit the authentication key of its parent process, although this may be changed by setting *authkey* to another byte string.

See *Authentication keys*.

terminate()

Terminate the process. On Unix this is done using the SIGTERM signal; on Windows *TerminateProcess()* is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

Warning: If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

Note that the *start()*, *join()*, *is_alive()*, *terminate()* and *exitcode* methods should only be called by the process that created the process object.

Example usage of some of the methods of *Process*:

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep, args=(1000,))
>>> print p, p.is_alive()
<Process(Process-1, initial)> False
>>> p.start()
>>> print p, p.is_alive()
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print p, p.is_alive()
<Process(Process-1, stopped[SIGTERM])> False
>>> p.exitcode == -signal.SIGTERM
True
```

exception multiprocessing.BufferTooShort

Exception raised by *Connection.recv_bytes_into()* when the supplied buffer object is too small for the message read.

If *e* is an instance of *BufferTooShort* then *e.args[0]* will give the message as a byte string.

Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use *Pipe()* (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The *Queue*, *multiprocessing.queues.SimpleQueue* and *JoinableQueue* types are multi-producer, multi-consumer FIFO queues modelled on the *Queue.Queue* class in the standard library. They differ in that *Queue* lacks the *task_done()* and *join()* methods introduced into Python 2.5's *Queue.Queue* class.

If you use `JoinableQueue` then you **must** call `JoinableQueue.task_done()` for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see [Managers](#).

Note: `multiprocessing` uses the usual `Queue.Empty` and `Queue.Full` exceptions to signal a timeout. They are not available in the `multiprocessing` namespace so you need to import them from `Queue`.

Note: When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a [manager](#).

- (1) After putting an object on an empty queue there may be an infinitesimal delay before the queue's `empty()` method returns `False` and `get_nowait()` can return without raising `Queue.Empty`.
 - (2) If multiple processes are enqueueing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.
-

Warning: If a process is killed using `Process.terminate()` or `os.kill()` while it is trying to use a `Queue`, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

Warning: As mentioned above, if a child process has put items on a queue (and it has not used `JoinableQueue.cancel_join_thread()`), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See [Programming guidelines](#).

For an example of the usage of queues for interprocess communication see [Examples](#).

`multiprocessing.Pipe([duplex])`

Returns a pair (`conn1`, `conn2`) of `Connection` objects representing the ends of a pipe.

If `duplex` is `True` (the default) then the pipe is bidirectional. If `duplex` is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

class `multiprocessing.Queue([maxsize])`

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual `Queue.Empty` and `Queue.Full` exceptions from the standard library's `Queue` module are raised to signal timeouts.

`Queue` implements all the methods of `Queue.Queue` except for `task_done()` and `join()`.

`qsize()`

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise `NotImplementedError` on Unix platforms like Mac OS X where `sem_getvalue()` is not implemented.

empty()

Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

full()

Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

put(obj[, block[, timeout]])

Put `obj` into the queue. If the optional argument `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until a free slot is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `Queue.Full` exception if no free slot was available within that time. Otherwise (`block` is `False`), put an item on the queue if a free slot is immediately available, else raise the `Queue.Full` exception (`timeout` is ignored in that case).

put_nowait(obj)

Equivalent to `put(obj, False)`.

get([block[, timeout]])

Remove and return an item from the queue. If optional args `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until an item is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `Queue.Empty` exception if no item was available within that time. Otherwise (`block` is `False`), return an item if one is immediately available, else raise the `Queue.Empty` exception (`timeout` is ignored in that case).

get_nowait()

Equivalent to `get(False)`.

`Queue` has a few additional methods not found in `Queue.Queue`. These methods are usually unnecessary for most code:

close()

Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

join_thread()

Join the background thread. This can only be used after `close()` has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call `cancel_join_thread()` to make `join_thread()` do nothing.

cancel_join_thread()

Prevent `join_thread()` from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see `join_thread()`.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to be lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

Note: This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a `Queue` will result in an `ImportError`. See [bpo-3770](#) for additional information. The same holds true for any of the specialized queue types listed below.

class multiprocessing.queues.SimpleQueue

It is a simplified *Queue* type, very close to a locked *Pipe*.

empty()

Return True if the queue is empty, False otherwise.

get()

Remove and return an item from the queue.

put(item)

Put *item* into the queue.

class multiprocessing.JoinableQueue([maxsize])

JoinableQueue, a *Queue* subclass, is a queue which additionally has *task_done()* and *join()* methods.

task_done()

Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each *get()* used to fetch a task, a subsequent call to *task_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task_done()* call was received for every item that had been *put()* into the queue).

Raises a *ValueError* if called more times than there were items placed in the queue.

join()

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls *task_done()* to indicate that the item was retrieved and all work on it is complete.

When the count of unfinished tasks drops to zero, *join()* unblocks.

Miscellaneous

multiprocessing.active_children()

Return list of all live children of the current process.

Calling this has the side effect of “joining” any processes which have already finished.

multiprocessing.cpu_count()

Return the number of CPUs in the system. May raise *NotImplementedError*.

multiprocessing.current_process()

Return the *Process* object corresponding to the current process.

An analogue of *threading.current_thread()*.

multiprocessing.freeze_support()

Add support for when a program which uses *multiprocessing* has been frozen to produce a Windows executable. (Has been tested with **py2exe**, **PyInstaller** and **cx_Freeze**.)

One needs to call this function straight after the `if __name__ == '__main__':` line of the main module. For example:

```
from multiprocessing import Process, freeze_support

def f():
    print 'hello world!'

if __name__ == '__main__':
```

(continues on next page)

(continued from previous page)

```
freeze_support()
Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise *RuntimeError*.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on Windows (the program has not been frozen), then `freeze_support()` has no effect.

`multiprocessing.set_executable()`

Sets the path of the Python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes. (Windows only)

Note: `multiprocessing` contains no analogues of `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, or `threading.local`.

Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using *Pipe* – see also *Listeners and Clients*.

class Connection

send(*obj*)

Send an object to the other end of the connection which should be read using `recv()`.

The object must be picklable. Very large pickles (approximately 32 MB+, though it depends on the OS) may raise a *ValueError* exception.

recv()

Return an object sent from the other end of the connection using `send()`. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

fileno()

Return the file descriptor or handle used by the connection.

close()

Close the connection.

This is called automatically when the connection is garbage collected.

poll(*[timeout]*)

Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies the maximum time in seconds to block. If *timeout* is *None* then an infinite timeout is used.

send_bytes(*buffer[, offset[, size]]*)

Send byte data from an object supporting the buffer interface as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from *buffer*. Very large buffers (approximately 32 MB+, though it depends on the OS) may raise a *ValueError* exception

recv_bytes (*[maxlength]*)

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then *IOError* is raised and the connection will no longer be readable.

recv_bytes_into (*buffer* [, *offset*])

Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

buffer must be an object satisfying the writable buffer interface. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a *BufferTooShort* exception is raised and the complete message is available as *e.args[0]* where *e* is the exception instance.

For example:

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes('thank you')
>>> a.recv_bytes()
'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

Warning: The *Connection.recv()* method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using *Pipe()* you should only use the *recv()* and *send()* methods after performing some sort of authentication. See *Authentication keys*.

Warning: If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for *threading* module.

Note that one can also create synchronization primitives by using a manager object – see *Managers*.

class multiprocessing.BoundedSemaphore([value])

A bounded semaphore object: a close analog of *threading.BoundedSemaphore*.

A solitary difference from its close analog exists: its *acquire* method's first argument is named *block* and it supports an optional second argument *timeout*, as is consistent with *Lock.acquire()*.

Note: On Mac OS X, this is indistinguishable from *Semaphore* because *sem_getvalue()* is not implemented on that platform.

class multiprocessing.Condition([lock])

A condition variable: a clone of *threading.Condition*.

If *lock* is specified then it should be a *Lock* or *RLock* object from *multiprocessing*.

class multiprocessing.Event

A clone of *threading.Event*. This method returns the state of the internal semaphore on exit, so it will always return *True* except if a timeout is given and the operation times out.

Changed in version 2.7: Previously, the method always returned *None*.

class multiprocessing.Lock

A non-recursive lock object: a close analog of *threading.Lock*. Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of *threading.Lock* as it applies to threads are replicated here in *multiprocessing.Lock* as it applies to either processes or threads, except as noted.

Note that *Lock* is actually a factory function which returns an instance of *multiprocessing.synchronize.Lock* initialized with a default context.

Lock supports the *context manager* protocol and thus may be used in *with* statements.

acquire (block=True, timeout=None)

Acquire a lock, blocking or non-blocking.

With the *block* argument set to *True* (the default), the method call will block until the lock is in an unlocked state, then set it to locked and return *True*. Note that the name of this first argument differs from that in *threading.Lock.acquire()*.

With the *block* argument set to *False*, the method call does not block. If the lock is currently in a locked state, return *False*; otherwise set the lock to a locked state and return *True*.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of *None* (the default) set the timeout period to infinite. The *timeout* argument has no practical implications if the *block* argument is set to *False* and is thus ignored. Returns *True* if the lock has been acquired or *False* if the timeout period has elapsed. Note that the *timeout* argument does not exist in this method's analog, *threading.Lock.acquire()*.

release ()

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in `threading.Lock.release()` except that when invoked on an unlocked lock, a `ValueError` is raised.

class multiprocessing.**RLock**

A recursive lock object: a close analog of `threading.RLock`. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that `RLock` is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the *context manager* protocol and thus may be used in `with` statements.

acquire (*block=True, timeout=None*)

Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of `threading.RLock.acquire()`, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in `Lock.acquire()`. Note that the *timeout* argument does not exist in this method's analog, `threading.RLock.acquire()`.

release ()

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An `AssertionError` is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (un-owned) state. Note that the type of exception raised in this situation differs from the implemented behavior in `threading.RLock.release()`.

class multiprocessing.**Semaphore** ([*value*])

A semaphore object: a close analog of `threading.Semaphore`.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block* and it supports an optional second argument *timeout*, as is consistent with `Lock.acquire()`.

Note: The `acquire()` method of `BoundedSemaphore`, `Lock`, `RLock` and `Semaphore` has a *timeout* parameter not supported by the equivalents in `threading`. The signature is `acquire(block=True, timeout=None)` with keyword parameters being acceptable. If *block* is `True` and *timeout* is not `None` then it specifies a timeout in seconds. If *block* is `False` then *timeout* is ignored.

On Mac OS X, `sem_timedwait` is unsupported, so calling `acquire()` with a *timeout* will emulate that function's behavior using a sleeping loop.

Note: If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to

`BoundedSemaphore.acquire()`, `Lock.acquire()`, `RLock.acquire()`, `Semaphore.acquire()`, `Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and `KeyboardInterrupt` will be raised.

This differs from the behaviour of `threading` where `SIGINT` will be ignored while the equivalent blocking calls are in progress.

Note: Some of this package’s functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. See [bpo-3770](#) for additional information.

Shared ctypes Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

`multiprocessing.Value` (*typecode_or_type*, **args*[, *lock*])

Return a `ctypes` object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object.

typecode_or_type determines the type of the returned object: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. **args* is passed on to the constructor for the type.

If *lock* is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

`multiprocessing.Array` (*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

Return a `ctypes` array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

typecode_or_type determines the type of the elements of the returned array: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword only argument.

Note that an array of `ctypes.c_char` has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

The multiprocessing.sharedctypes module

The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

Note: Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray` (*typecode_or_type*, *size_or_initializer*)

Return a ctypes array allocated from shared memory.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.RawValue` (*typecode_or_type*, **args*)

Return a ctypes object allocated from shared memory.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the `array` module. **args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

`multiprocessing.sharedctypes.Array` (*typecode_or_type*, *size_or_initializer*, **args*[, *lock*])

The same as `RawArray()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.Value` (*typecode_or_type*, **args*[, *lock*])

The same as `RawValue()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.copy` (*obj*)

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

`multiprocessing.sharedctypes.synchronized` (*obj*[, *lock*])

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a `multiprocessing.RLock` object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of `ctypes.Structure`.)

| ctypes | sharedctypes using type | sharedctypes using typecode |
|-----------------------------------|---|---------------------------------------|
| <code>c_double(2.4)</code> | <code>RawValue(c_double, 2.4)</code> | <code>RawValue('d', 2.4)</code> |
| <code>MyStruct(4, 6)</code> | <code>RawValue(MyStruct, 4, 6)</code> | |
| <code>(c_short * 7)()</code> | <code>RawArray(c_short, 7)</code> | <code>RawArray('h', 7)</code> |
| <code>(c_int * 3)(9, 2, 8)</code> | <code>RawArray(c_int, (9, 2, 8))</code> | <code>RawArray('i', (9, 2, 8))</code> |

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value *= 2
    x.value *= 2
    s.value = s.value.upper()
    for a in A:
        a.x *= 2
        a.y *= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', 'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375,9.5)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print n.value
    print x.value
    print s.value
    print [(a.x, a.y) for a in A]
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

Managers

Managers provide a way to create data which can be shared between different processes. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`

Returns a started *SyncManager* object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the `multiprocessing.managers` module:

class `multiprocessing.managers.BaseManager` (`[address[, authkey]]`)

Create a BaseManager object.

Once created one should call `start()` or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If *address* is `None` then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is `None` then `current_process().authkey`. Otherwise *authkey* is used and it must be a string.

start (`[initializer[, initargs]]`)

Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

get_server ()

Returns a `Server` object which represents the actual server under the control of the `Manager`. The `Server` object supports the `serve_forever()` method:

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=(' ', 50000), authkey='abc')
>>> server = manager.get_server()
>>> server.serve_forever()
```

`Server` additionally has an *address* attribute.

connect ()

Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000), authkey='abc')
>>> m.connect()
```

shutdown ()

Stop the process used by the manager. This is only available if `start()` has been used to start the server process.

This can be called multiple times.

register (`typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]]`)

A classmethod which can be used for registering a type or callable with the manager class.

typeid is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be created using the `from_address()` classmethod or if the *create_method* argument is `False` then this can be left

as None.

proxytype is a subclass of *BaseProxy* which is used to create proxies for shared objects with this *typeid*. If None then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this *typeid* should be allowed to access using *BaseProxy._callmethod()*. (If *exposed* is None then *proxytype._exposed_* is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a *__call__()* method and whose name does not begin with *'_'*.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method_to_typeid* is None then *proxytype._method_to_typeid_* is used instead if it exists.) If a method’s name is not a key of this mapping or if the mapping is None then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is True.

BaseManager instances also have one read-only property:

address

The address used by the manager.

class multiprocessing.managers.SyncManager

A subclass of *BaseManager* which can be used for the synchronization of processes. Objects of this type are returned by *multiprocessing.Manager()*.

It also supports creation of shared lists and dictionaries.

BoundedSemaphore (*[value]*)

Create a shared *threading.BoundedSemaphore* object and return a proxy for it.

Condition (*[lock]*)

Create a shared *threading.Condition* object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a *threading.Lock* or *threading.RLock* object.

Event ()

Create a shared *threading.Event* object and return a proxy for it.

Lock ()

Create a shared *threading.Lock* object and return a proxy for it.

Namespace ()

Create a shared *Namespace* object and return a proxy for it.

Queue (*[maxsize]*)

Create a shared *Queue.Queue* object and return a proxy for it.

RLock ()

Create a shared *threading.RLock* object and return a proxy for it.

Semaphore (*[value]*)

Create a shared *threading.Semaphore* object and return a proxy for it.

Array (*typecode, sequence*)

Create an array and return a proxy for it.

Value (*typecode, value*)

Create an object with a writable *value* attribute and return a proxy for it.

dict ()

dict (*mapping*)

dict (*sequence*)

Create a shared dict object and return a proxy for it.

list ()

list (*sequence*)

Create a shared list object and return a proxy for it.

Note: Modifications to mutable values or items in dict and list proxies will not be propagated through the manager, because the proxy has no way of knowing when its values or items are modified. To modify such an item, you can re-assign the modified object to the container proxy:

```
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, but by
# reassigning the dictionary, the proxy is notified of the change
lproxy[0] = d
```

class multiprocessing.managers.Namespace

A type that can register with *SyncManager*.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with '_' will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3      # this is an attribute of the proxy
>>> print Global
Namespace(x=10, y='hello')
```

Customized managers

To create one's own manager, one creates a subclass of *BaseManager* and uses the *register()* classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass(object):
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass
```

(continues on next page)

(continued from previous page)

```
MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    manager = MyManager()
    manager.start()
    maths = manager.Maths()
    print maths.add(4, 3)          # prints 7
    print maths.mul(7, 8)         # prints 56
```

Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```
>>> from multiprocessing.managers import BaseManager
>>> import Queue
>>> queue = Queue.Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey='abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super(Worker, self).__init__()
```

(continues on next page)

(continued from previous page)

```

...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey='abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()

```

Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). A proxy can usually be used in most of the same ways that its referent can:

```

>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print l
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print repr(l)
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]

```

Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. Note, however, that if a proxy is sent to the corresponding manager's process then unpickling it will produce the referent itself. This means, for example, that one shared object can contain a second:

```

>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)           # referent of a now contains referent of b
>>> print a, b
[[]] []
>>> b.append('hello')
>>> print a, b
[['hello']] ['hello']

```

Note: The proxy types in `multiprocessing` do nothing to support comparisons by value. So, for instance, we have:

```

>>> manager.list([1,2,3]) == [1,2,3]
False

```

One should just use a copy of the referent instead when making comparisons.

class multiprocessing.managers.**BaseProxy**

Proxy objects are instances of subclasses of *BaseProxy*.

_callmethod (*methodname* [, *args* [, *kws*]])

Call and return the result of a method of the proxy's referent.

If proxy is a proxy whose referent is obj then the expression

```
proxy._callmethod(methodname, args, kws)
```

will evaluate the expression

```
getattr(obj, methodname) (*args, **kws)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the *method_to_typeid* argument of *BaseManager.register()*.

If an exception is raised by the call, then is re-raised by *_callmethod()*. If some other exception is raised in the manager's process then this is converted into a *RemoteError* exception and is raised by *_callmethod()*.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of *_callmethod()*:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getslice__', (2, 7))    # equiv to `l[2:7]`
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))      # equiv to `l[20]`
Traceback (most recent call last):
...
IndexError: list index out of range
```

_getvalue ()

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

__repr__ ()

Return a representation of the proxy object.

__str__ ()

Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

class `multiprocessing.Pool` (`[processes[, initializer[, initargs[, maxtasksperchild]]]`)

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

`processes` is the number of worker processes to use. If `processes` is `None` then the number returned by `cpu_count()` is used. If `initializer` is not `None` then each worker process will call `initializer(*initargs)` when it starts.

Note that the methods of the pool object should only be called by the process which created the pool.

New in version 2.7: `maxtasksperchild` is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default `maxtasksperchild` is `None`, which means worker processes will live as long as the pool.

Note: Worker processes within a `Pool` typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, `mod_wsgi`, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The `maxtasksperchild` argument to the `Pool` exposes this ability to the end user.

apply (`func[, args[, kwds]]`)

Equivalent of the `apply()` built-in function. It blocks until the result is ready, so `apply_async()` is better suited for performing work in parallel. Additionally, `func` is only executed in one of the workers of the pool.

apply_async (`func[, args[, kwds[, callback]]]`)

A variant of the `apply()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it (unless the call failed). `callback` should complete immediately since otherwise the thread which handles the results will get blocked.

map (`func, iterable[, chunksize]`)

A parallel equivalent of the `map()` built-in function (it supports only one `iterable` argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting `chunksize` to a positive integer.

map_async (`func, iterable[, chunksize[, callback]]`)

A variant of the `map()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it (unless the call failed). `callback` should complete immediately since otherwise the thread which handles the results will get blocked.

imap (`func, iterable[, chunksize]`)

An equivalent of `itertools.imap()`.

The `chunksize` argument is the same as the one used by the `map()` method. For very long iterables using a large value for `chunksize` can make the job complete **much** faster than using the default value of 1.

Also if `chunksize` is 1 then the `next()` method of the iterator returned by the `imap()` method has an optional `timeout` parameter: `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within `timeout` seconds.

imap_unordered (*func*, *iterable*[, *chunksize*])

The same as *imap*() except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”).

close()

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

terminate()

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected *terminate*() will be called immediately.

join()

Wait for the worker processes to exit. One must call *close*() or *terminate*() before using *join*().

class multiprocessing.pool.**AsyncResult**

The class of the result returned by *Pool.apply_async*() and *Pool.map_async*().

get ([*timeout*])

Return the result when it arrives. If *timeout* is not None and the result does not arrive within *timeout* seconds then *multiprocessing.TimeoutError* is raised. If the remote call raised an exception then that exception will be reraised by *get*().

wait ([*timeout*])

Wait until the result is available or until *timeout* seconds pass.

ready()

Return whether the call has completed.

successful()

Return whether the call completed without raising an exception. Will raise *AssertionError* if the result is not ready.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    pool = Pool(processes=4)           # start 4 worker processes

    result = pool.apply_async(f, (10,)) # evaluate "f(10)" asynchronously in a
↪ single process
    print result.get(timeout=1)         # prints "100" unless your computer is
↪ *very* slow

    print pool.map(f, range(10))       # prints "[0, 1, 4, ..., 81]"

    it = pool.imap(f, range(10))
    print it.next()                    # prints "0"
    print it.next()                    # prints "1"
    print it.next(timeout=1)           # prints "4" unless your computer is *very*
↪ slow

    result = pool.apply_async(time.sleep, (10,))
    print result.get(timeout=1)         # raises multiprocessing.TimeoutError
```

Listeners and Clients

Usually message passing between processes is done using queues or by using *Connection* objects returned by *Pipe()*.

However, the *multiprocessing.connection* module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes, and also has support for *digest authentication* using the *hmac* module.

`multiprocessing.connection.deliver_challenge(connection, authkey)`

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise *AuthenticationError* is raised.

`multiprocessing.connection.answer_challenge(connection, authkey)`

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then *AuthenticationError* is raised.

`multiprocessing.connection.Client(address[, family[, authenticate[, authkey]]])`

Attempt to set up a connection to the listener which is using address *address*, returning a *Connection*.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See *Address Formats*)

If *authenticate* is *True* or *authkey* is a string then digest authentication is used. The key used for authentication will be either *authkey* or `current_process().authkey` if *authkey* is *None*. If authentication fails then *AuthenticationError* is raised. See *Authentication keys*.

class `multiprocessing.connection.Listener([address[, family[, backlog[, authenticate[, authkey]]]])`

A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

address is the address to be used by the bound socket or named pipe of the listener object.

Note: If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

family is the type of socket (or named pipe) to use. This can be one of the strings 'AF_INET' (for a TCP socket), 'AF_UNIX' (for a Unix domain socket) or 'AF_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is *None* then the family is inferred from the format of *address*. If *address* is also *None* then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if *family* is 'AF_UNIX' and *address* is *None* then the socket will be created in a private temporary directory created using *tempfile.mkstemp()*.

If the listener object uses a socket then *backlog* (1 by default) is passed to the *listen()* method of the socket once it has been bound.

If *authenticate* is *True* (*False* by default) or *authkey* is not *None* then digest authentication is used.

If *authkey* is a string then it will be used as the authentication key; otherwise it must be *None*.

If *authkey* is *None* and *authenticate* is *True* then `current_process().authkey` is used as the authentication key. If *authkey* is *None* and *authenticate* is *False* then no authentication is done. If authentication fails then *AuthenticationError* is raised. See *Authentication keys*.

accept()

Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

close()

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address

The address which is being used by the Listener object.

last_accepted

The address from which the last accepted connection came. If this is unavailable then it is `None`.

The module defines the following exceptions:

exception multiprocessing.connection.ProcessError

The base class of all *multiprocessing* exceptions.

exception multiprocessing.connection.BufferTooShort

Exception raised by *Connection.recv_bytes_into()* when the supplied buffer object is too small for the message read.

exception multiprocessing.connection.AuthenticationError

Raised when there is an authentication error.

exception multiprocessing.connection.TimeoutError

Raised by methods with a timeout when the timeout expires.

Examples

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)      # family is deduced to be 'AF_INET'
listener = Listener(address, authkey='secret password')

conn = listener.accept()
print 'connection accepted from', listener.last_accepted

conn.send([2.25, None, 'junk', float])

conn.send_bytes('hello')

conn.send_bytes(array('i', [42, 1729]))

conn.close()
listener.close()
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)
conn = Client(address, authkey='secret password')

print conn.recv()                # => [2.25, None, 'junk', float]

print conn.recv_bytes()          # => 'hello'
```

(continues on next page)

(continued from previous page)

```
arr = array('i', [0, 0, 0, 0, 0])
print conn.recv_bytes_into(arr)      # => 8
print arr                            # => array('i', [42, 1729, 0, 0, 0])

conn.close()
```

Address Formats

- An 'AF_INET' address is a tuple of the form (hostname, port) where *hostname* is a string and *port* is an integer.
- An 'AF_UNIX' address is a string representing a filename on the filesystem.
- An 'AF_PIPE' address is a string of the form r'\.\pipe{PipeName}'. To use *Client()* to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form r'\ServerName\pipe{PipeName}' instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

Authentication keys

When one uses *Connection.recv()*, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore *Listener* and *Client()* use the *hmac* module to provide digest authentication.

An authentication key is a string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of *current_process().authkey* is used (see *Process*). This value will be automatically inherited by any *Process* object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using *os.urandom()*.

Logging

Some support for logging is available. Note, however, that the *logging* package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

multiprocessing.get_logger()

Returns the logger used by *multiprocessing*. If necessary, a new one will be created.

When first created the logger has level *logging.NOTSET* and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

multiprocessing.log_to_stderr()

This function performs a call to *get_logger()* but in addition to returning the logger created by

`get_logger`, it adds a handler which sends output to `sys.stderr` using format `'[%(levelname)s/%(processName)s] %(message)s'`.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pypm-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

In addition to having these two logging functions, the `multiprocessing` also exposes two additional logging level attributes. These are `SUBWARNING` and `SUBDEBUG`. The table below illustrates where these fit in the normal level hierarchy.

| Level | Numeric value |
|-------------------------|---------------|
| <code>SUBWARNING</code> | 25 |
| <code>SUBDEBUG</code> | 5 |

For a full table of logging levels, see the `logging` module.

These additional logging levels are used primarily for certain debug messages within the `multiprocessing` module. Below is the same example as above, except with `SUBDEBUG` enabled:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(multiprocessing.SUBDEBUG)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pypm-...
[INFO/SyncManager-...] manager serving at '/.../pypm-djGBXN/listener-...'
>>> del m
[SUBDEBUG/MainProcess] finalizer calling ...
[INFO/MainProcess] sending shutdown message to manager
[DEBUG/SyncManager-...] manager received shutdown message
[SUBDEBUG/SyncManager-...] calling <Finalize object, callback=unlink, ...
[SUBDEBUG/SyncManager-...] finalizer calling <built-in function unlink> ...
[SUBDEBUG/SyncManager-...] calling <Finalize object, dead>
[SUBDEBUG/SyncManager-...] finalizer calling <function rmtree at 0x5aa730> ...
[INFO/SyncManager-...] manager exiting with exitcode 0
```

The `multiprocessing.dummy` module

`multiprocessing.dummy` replicates the API of `multiprocessing` but is no more than a wrapper around the `threading` module.

16.6.3 Programming guidelines

There are certain guidelines and idioms which should be adhered to when using *multiprocessing*.

All platforms

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives from the *threading* module.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or *active_children()* is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's *Process.is_alive* will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

On Windows many types from *multiprocessing* need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the *Process.terminate* method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using *Process.terminate* on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the *cancel_join_thread()* method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```

from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                # this deadlocks
    obj = queue.get()

```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```

from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()

```

should be rewritten as

```

from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()

```

Beware of replacing `sys.stdin` with a “file like object”

`multiprocessing` originally unconditionally called:

```
os.close(sys.stdin.fileno())
```

in the `multiprocessing.Process._bootstrap()` method — this resulted in issues with processes-in-processes. This has been changed to:

```

sys.stdin.close()
sys.stdin = open(os.devnull)

```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace `sys.stdin()` with a “file-like object” with output buffering. This danger is that if multiple processes call `close()` on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see [bpo-5155](#), [bpo-5313](#) and [bpo-5331](#)

Windows

Since Windows lacks `os.fork()` it has a few extra restrictions:

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. This means, in particular, that bound or unbound methods cannot be used directly as the `target` argument on Windows — just define a function and use that instead.

Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, under Windows running the following module would fail with a `RuntimeError`:

```
from multiprocessing import Process

def foo():
    print 'hello'

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_support

def foo():
```

(continues on next page)

(continued from previous page)

```

    print 'hello'

if __name__ == '__main__':
    freeze_support()
    p = Process(target=foo)
    p.start()

```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

16.6.4 Examples

Demonstration of how to create and use customized managers and proxies:

```

#
# This module shows how to use arbitrary callables with a subclass of
# `BaseManager`.
#
# Copyright (c) 2006-2008, R Oudkerk
# All rights reserved.
#

from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo(object):
    def f(self):
        print 'you called Foo.f()'
    def g(self):
        print 'you called Foo.g()'
    def _h(self):
        print 'you called Foo._h()'

# A simple generator function
def baz():
    for i in xrange(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ('next', '__next__')
    def __iter__(self):
        return self
    def next(self):
        return self._callmethod('next')
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module

```

(continues on next page)

(continued from previous page)

```

def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print '-' * 20

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print '-' * 20

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print '-' * 20

    it = manager.baz()
    for i in it:
        print '<%d>' % i,
    print

    print '-' * 20

    op = manager.operator()
    print 'op.add(23, 45) =', op.add(23, 45)
    print 'op.pow(2, 94) =', op.pow(2, 94)
    print 'op.getslice(range(10), 2, 6) =', op.getslice(range(10), 2, 6)
    print 'op.repeat(range(5), 3) =', op.repeat(range(5), 3)
    print 'op._exposed_ =', op._exposed_

```

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```

#
# Simple example which uses a pool of workers to carry out some tasks.
#
# Notice that the results will probably not come out of the output
# queue in the same in the same order as the corresponding tasks were
# put on the input queue.  If it is important to get the results back
# in the original order then consider using `Pool.map()` or
# `Pool.imap()` (which will save on the amount of code needed anyway).

16.7 mmap — Memory-mapped file support

Memory-mapped file objects behave like both strings and like file objects. Unlike normal string objects, however, these are mutable. You can use `mmap` objects in most places where strings are expected; for example, you can use the `re` module to search through a memory-mapped file. Since they're mutable, you can change a single character by doing `obj[index] = 'a'`, or change a substring by assigning to a slice: `obj[i1:i2] = '...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the

`os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

Note: If you want to create a memory-mapping for a writable, buffered file, you should `flush()` the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, `access` may be specified as an optional keyword parameter. `access` accepts one of three values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively. `access` can be used on both Unix and Windows. If `access` is not specified, Windows `mmap` returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a `TypeError` exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but does not update the underlying file.

Changed in version 2.5: To map anonymous memory, -1 should be passed as the `fileno` along with the `length`.

Changed in version 2.6: `mmap.mmap` has formerly been a factory function creating `mmap` objects. Now `mmap.mmap` is the class itself.

class `mmap.mmap` (`fileno`, `length`[, `tagname`[, `access`[, `offset`]]])

(Windows version) Maps `length` bytes from the file specified by the file handle `fileno`, and creates a `mmap` object. If `length` is larger than the current size of the file, the file is extended to contain `length` bytes. If `length` is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

`tagname`, if specified and not `None`, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or `None`, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

`offset` may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. `offset` defaults to 0. `offset` must be a multiple of the `ALLOCATIONGRANULARITY`.

class `mmap.mmap` (`fileno`, `length`[, `flags`[, `prot`[, `access`[, `offset`]]]])

(Unix version) Maps `length` bytes from the file specified by the file descriptor `fileno`, and returns a `mmap` object. If `length` is 0, the maximum length of the map will be the current size of the file when `mmap` is called.

`flags` specifies the nature of the mapping. `MAP_PRIVATE` creates a private copy-on-write mapping, so changes to the contents of the `mmap` object will be private to this process, and `MAP_SHARED` creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is `MAP_SHARED`.

`prot`, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. `prot` defaults to `PROT_READ | PROT_WRITE`.

`access` may be specified in lieu of `flags` and `prot` as an optional keyword parameter. It is an error to specify both `flags`, `prot` and `access`. See the description of `access` above for information on how to use this parameter.

`offset` may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. `offset` defaults to 0. `offset` must be a multiple of `ALLOCATIONGRANULARITY` which is equal to `PAGESIZE` on Unix systems.

To ensure validity of the created memory mapping the file specified by the descriptor `fileno` is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap`:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
```

(continues on next page)

(continued from previous page)

```

f.write("Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print mm.readline() # prints "Hello Python!"
    # read content via slice notation
    print mm[:5] # prints "Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = " world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print mm.readline() # prints "Hello world!"
    # close the map
    mm.close()

```

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```

import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write("Hello world!")

pid = os.fork()

if pid == 0: # In a child process
    mm.seek(0)
    print mm.readline()

    mm.close()

```

Memory-mapped file objects support the following methods:

close()

Closes the mmap. Subsequent calls to other methods of the object will result in a `ValueError` exception being raised. This will not close the open file.

find(*string*[, *start*[, *end*]])

Returns the lowest index in the object where the substring *string* is found, such that *string* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

flush([*offset*, *size*])

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed. *offset* must be a multiple of the `PAGESIZE` or `ALLOCATIONGRANULARITY`.

(Windows version) A nonzero value returned indicates success; zero indicates failure.

(Unix version) A zero value is returned to indicate success. An exception is raised when the call failed.

move(*dest*, *src*, *count*)

Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with `ACCESS_READ`, then calls to move will raise a `TypeError` exception.

read (*num*)

Return a string containing up to *num* bytes starting from the current file position; the file position is updated to point after the bytes that were returned.

read_byte ()

Returns a string of length 1 containing the character at the current file position, and advances the file position by 1.

readline ()

Returns a single line, starting at the current file position and up to the next newline.

resize (*newsize*)

Resizes the map and the underlying file, if any. If the mmap was created with `ACCESS_READ` or `ACCESS_COPY`, resizing the map will raise a `TypeError` exception.

rfind (*string* [, *start* [, *end*]])

Returns the highest index in the object where the substring *string* is found, such that *string* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns -1 on failure.

seek (*pos* [, *whence*])

Set the file's current position. *whence* argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).

size ()

Return the length of the file, which can be larger than the size of the memory-mapped area.

tell ()

Returns the current position of the file pointer.

write (*string*)

Write the bytes in *string* into memory at the current position of the file pointer; the file position is updated to point after the bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.

write_byte (*byte*)

Write the single-character string *byte* into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.

16.8 readline — GNU readline interface

The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the `rlcompleter` module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the `raw_input()` and `input()` built-in functions.

Note: The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On MacOS X the `readline` module detects which library is being used at run time.

The configuration file for `libedit` is different from that of GNU readline. If you programmatically load configuration strings you can check for the text “libedit” in `readline.__doc__` to differentiate between GNU readline and libedit.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See [Readline Init File](#) in the GNU Readline manual for information about the format and allowable constructs of that file, and

the capabilities of the Readline library in general.

16.8.1 Init file

The following functions relate to the init file and user configuration:

`readline.parse_and_bind(string)`
Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.read_init_file([filename])`
Execute a readline initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

16.8.2 Line buffer

The following functions operate on the line buffer:

`readline.get_line_buffer()`
Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.insert_text(string)`
Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

`readline.redisplay()`
Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

16.8.3 History file

The following functions operate on a history file:

`readline.read_history_file([filename])`
Load a readline history file, and append it to the history list. The default filename is `~/.history`. This calls `read_history()` in the underlying library.

`readline.write_history_file([filename])`
Save the history list to a readline history file, overwriting any existing file. The default filename is `~/.history`. This calls `write_history()` in the underlying library.

`readline.get_history_length()`
`readline.set_history_length(length)`
Set or return the desired number of lines to save in the history file. The `write_history_file()` function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

16.8.4 History list

The following functions operate on a global history list:

`readline.clear_history()`
Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

New in version 2.4.

`readline.get_current_history_length()`

Return the number of items currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

New in version 2.3.

`readline.get_history_item(index)`

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

New in version 2.3.

`readline.remove_history_item(pos)`

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

New in version 2.4.

`readline.replace_history_item(pos, line)`

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

New in version 2.4.

`readline.add_history(line)`

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

16.8.5 Startup hooks

New in version 2.3.

`readline.set_startup_hook([function])`

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before readline prints the first prompt.

`readline.set_pre_input_hook([function])`

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before readline starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

16.8.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, Readline is set up to be used by `rlcompleter` to complete Python identifiers for the interactive interpreter. If the `readline` module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.set_completer([function])`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the *entry_func* callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

`readline.get_completer()`

Get the completer function, or None if no completer function has been set.

New in version 2.3.

`readline.get_completion_type()`

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

New in version 2.6.

`readline.get_begidx()`

`readline.get_endidx()`

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library.

`readline.set_completer_delims(string)`

`readline.get_completer_delims()`

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

`readline.set_completion_display_matches_hook([function])`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or None, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

New in version 2.6.

16.8.7 Example

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.pyhist` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), ".pyhist")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except IOError:
    pass
import atexit
atexit.register(readline.write_history_file, histfile)
del os, histfile
```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```
import code
import readline
```

(continues on next page)

(continued from previous page)

```

import atexit
import os

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except IOError:
                pass
        atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
        readline.set_history_length(1000)
        readline.write_history_file(histfile)

```

16.9 rlcompleter — Completion function for GNU readline

Source code: [Lib/rlcompleter.py](#)

The *rlcompleter* module defines a completion function suitable for the *readline* module by completing valid Python identifiers and keywords.

When this module is imported on a Unix platform with the *readline* module available, an instance of the *Completer* class is automatically created and its *complete()* method is set as the *readline* completer.

Example:

```

>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__         readline.insert_text(      readline.set_completer(
readline.__name__         readline.parse_and_bind(
>>> readline.

```

The *rlcompleter* module is designed for use with Python's interactive mode. A user can add the following lines to his or her initialization file (identified by the *PYTHONSTARTUP* environment variable) to get automatic Tab completion:

```

try:
    import readline
except ImportError:
    print "Module readline not available."
else:
    import rlcompleter
    readline.parse_and_bind("tab: complete")

```

On platforms without `readline`, the `Completer` class defined by this module can still be used for custom purposes.

16.9.1 Completer Objects

Completer objects have the following method:

`Completer.complete(text, state)`

Return the *state*th completion for *text*.

If called for *text* that doesn't include a period character ('.'), it will complete from names currently defined in `__main__`, `__builtin__` and keywords (as defined by the `keyword` module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()` up to the last part, and find matches for the rest via the `dir()` function. Any exception raised during the evaluation of the expression is caught, silenced and `None` is returned.

INTERPROCESS COMMUNICATION AND NETWORKING

The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. [signal](#) and [subprocess](#). Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

17.1 [subprocess](#) — Subprocess management

New in version 2.4.

The [subprocess](#) module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```
os.system
os.spawn*
os.popen*
popen2.*
commands.*
```

Information about how this module can be used to replace the older functions can be found in the [subprocess-replacements](#) section.

See also:

POSIX users (Linux, BSD, etc.) are strongly encouraged to install and use the much more recent [subprocess32](#) module instead of the version included with python 2.7. It is a drop in replacement with better behavior in many situations.

PEP 324 – PEP proposing the subprocess module

17.1.1 Using the [subprocess](#) Module

The recommended way to launch subprocesses is to use the following convenience functions. For more advanced use cases when these do not meet your needs, use the underlying [Popen](#) interface.

`subprocess.call(args, *, stdin=None, stdout=None, stderr=None, shell=False)`

Run the command described by *args*. Wait for command to complete, then return the `returncode` attribute.

The arguments shown above are merely the most common ones, described below in [Frequently Used Arguments](#) (hence the slightly odd notation in the abbreviated signature). The full function signature is the same as that of the [Popen](#) constructor - this functions passes all supplied arguments directly through to that interface.

Examples:

```
>>> subprocess.call(["ls", "-l"])
0

>>> subprocess.call("exit 1", shell=True)
1
```

Warning: Using `shell=True` can be a security hazard. See the warning under *Frequently Used Arguments* for details.

Note: Do not use `stdout=PIPE` or `stderr=PIPE` with this function as that can deadlock based on the child process output volume. Use *Popen* with the `communicate()` method when you need pipes.

`subprocess.check_call` (*args*, *, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*)

Run command with arguments. Wait for command to complete. If the return code was zero then return, otherwise raise *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute.

The arguments shown above are merely the most common ones, described below in *Frequently Used Arguments* (hence the slightly odd notation in the abbreviated signature). The full function signature is the same as that of the *Popen* constructor - this function passes all supplied arguments directly through to that interface.

Examples:

```
>>> subprocess.check_call(["ls", "-l"])
0

>>> subprocess.check_call("exit 1", shell=True)
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1
```

New in version 2.5.

Warning: Using `shell=True` can be a security hazard. See the warning under *Frequently Used Arguments* for details.

Note: Do not use `stdout=PIPE` or `stderr=PIPE` with this function as that can deadlock based on the child process output volume. Use *Popen* with the `communicate()` method when you need pipes.

`subprocess.check_output` (*args*, *, *stdin=None*, *stderr=None*, *shell=False*, *universal_newlines=False*)

Run command with arguments and return its output as a byte string.

If the return code was non-zero it raises a *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute and any output in the *output* attribute.

The arguments shown above are merely the most common ones, described below in *Frequently Used Arguments* (hence the slightly odd notation in the abbreviated signature). The full function signature is largely the same as that of the *Popen* constructor, except that *stdout* is not permitted as it is used internally. All other supplied arguments are passed directly through to the *Popen* constructor.

Examples:

```
>>> subprocess.check_output(["echo", "Hello World!"])
'Hello World!\n'

>>> subprocess.check_output("exit 1", shell=True)
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1
```

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

New in version 2.7.

Warning: Using `shell=True` can be a security hazard. See the warning under *Frequently Used Arguments* for details.

Note: Do not use `stderr=PIPE` with this function as that can deadlock based on the child process error volume. Use *Popen* with the `communicate()` method when you need a `stderr` pipe.

`subprocess.PIPE`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *Popen* and indicates that a pipe to the standard stream should be opened.

`subprocess.STDOUT`

Special value that can be used as the *stderr* argument to *Popen* and indicates that standard error should go into the same handle as standard output.

exception `subprocess.CalledProcessError`

Exception raised when a process run by *check_call()* or *check_output()* returns a non-zero exit status.

returncode

Exit status of the child process.

cmd

Command that was used to spawn the child process.

output

Output of the child process if this exception is raised by *check_output()*. Otherwise, `None`.

Frequently Used Arguments

To support a wide variety of use cases, the *Popen* constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

args is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either *shell* must be *True* (see below) or else the string must simply name the program to be executed without specifying any arguments.

`stdin`, `stdout` and `stderr` specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are `PIPE`, an existing file descriptor (a positive integer), an existing file object, and `None`. `PIPE` indicates that a new pipe to the child should be created. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, `stderr` can be `STDOUT`, which indicates that the `stderr` data from the child process should be captured into the same file handle as for `stdout`.

When `stdout` or `stderr` are pipes and `universal_newlines` is `True` then all line endings will be converted to `'\n'` as described for the `universal_newlines` `'U'` mode argument to `open()`.

If `shell` is `True`, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of `~` to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, `glob`, `fnmatch`, `os.walk()`, `os.path.expandvars()`, `os.path.expanduser()`, and `shutil`).

Warning: Executing shell commands that incorporate unsanitized input from an untrusted source makes a program vulnerable to [shell injection](#), a serious security flaw which can result in arbitrary command execution. For this reason, the use of `shell=True` is **strongly discouraged** in cases where the command string is constructed from external input:

```
>>> from subprocess import call
>>> filename = input("What file would you like to display?\n")
What file would you like to display?
non_existent; rm -rf / #
>>> call("cat " + filename, shell=True) # Uh-oh. This will end badly...
```

`shell=False` disables all shell based features, but does not suffer from this vulnerability; see the Note in the `Popen` constructor documentation for helpful hints in getting `shell=False` to work.

When using `shell=True`, `pipes.quote()` can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

These options, along with all of the other options, are described in more detail in the `Popen` constructor documentation.

Popen Constructor

The underlying process creation and management in this module is handled by the `Popen` class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

```
class subprocess.Popen(args, bufsize=0, executable=None, stdin=None, stdout=None, stderr=None,
                        preexec_fn=None, close_fds=False, shell=False, cwd=None, env=None, uni-
                        versal_newlines=False, startupinfo=None, creationflags=0)
```

Execute a child program in a new process. On Unix, the class uses `os.execvp()`-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to `Popen` are as follows.

`args` should be a sequence of program arguments or else a single string. By default, the program to execute is the first item in `args` if `args` is a sequence. If `args` is a string, the interpretation is platform-dependent and described below. See the `shell` and `executable` arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass `args` as a sequence.

On Unix, if `args` is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

Note: `shlex.split()` can be useful when determining the correct tokenization for *args*, especially in complex cases:

```
>>> import shlex, subprocess
>>> command_line = raw_input()
/bin/vikings -input eggs.txt -output "spam spam.txt" -cmd "echo '$MONEY'"
>>> args = shlex.split(command_line)
>>> print args
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', "echo '
→$MONEY'"]
>>> p = subprocess.Popen(args) # Success!
```

Note in particular that options (such as *-input*) and arguments (such as *eggs.txt*) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the *echo* command shown above) are single list elements.

On Windows, if *args* is a sequence, it will be converted to a string in a manner described in [Converting an argument sequence to a string on Windows](#). This is because the underlying `CreateProcess()` operates on strings.

The *shell* argument (which defaults to `False`) specifies whether to use the shell as the program to execute. If *shell* is `True`, it is recommended to pass *args* as a string rather than as a sequence.

On Unix with *shell*=`True`, the shell defaults to `/bin/sh`. If *args* is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, *Popen* does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with *shell*=`True`, the COMSPEC environment variable specifies the default shell. The only time you need to specify *shell*=`True` on Windows is when the command you wish to execute is built into the shell (e.g. *dir* or *copy*). You do not need *shell*=`True` to run a batch file or console-based executable.

Warning: Passing *shell*=`True` can be a security hazard if combined with untrusted input. See the warning under [Frequently Used Arguments](#) for details.

bufsize, if given, has the same meaning as the corresponding argument to the built-in `open()` function: 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size. A negative *bufsize* means to use the system default, which usually means fully buffered. The default value for *bufsize* is 0 (unbuffered).

Note: If you experience performance issues, it is recommended that you try to enable buffering by setting *bufsize* to either -1 or a large enough positive value (such as 4096).

The *executable* argument specifies a replacement program to execute. It is very seldom needed. When *shell*=`False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On Unix, the *args* name becomes the display name for the executable in utilities such as *ps*. If *shell*=`True`, on Unix the *executable* argument specifies a replacement shell for the default `/bin/sh`.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are *PIPE*, an existing file descriptor (a positive integer), an existing file object, and *None*. *PIPE* indicates that a new pipe to the child should be created. With the default settings of *None*, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be *STDOUT*, which indicates that the *stderr* data from the child process should be captured into the same file handle as for *stdout*.

If *preexec_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (Unix only)

If *close_fds* is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (Unix only). Or, on Windows, if *close_fds* is true then no handles will be inherited by the child process. Note that on Windows, you cannot set *close_fds* to true and also redirect the standard handles by setting *stdin*, *stdout* or *stderr*.

If *cwd* is not *None*, the child's current directory will be changed to *cwd* before it is executed. Note that this directory is not considered when searching the executable, so you can't specify the program's path relative to *cwd*.

If *env* is not *None*, it must be a mapping that defines the environment variables for the new process; these are used instead of inheriting the current process' environment, which is the default behavior.

Note: If specified, *env* must provide any variables required for the program to execute. On Windows, in order to run a *side-by-side assembly* the specified *env* **must** include a valid *SystemRoot*.

If *universal_newlines* is *True*, the file objects *stdout* and *stderr* are opened as text files in *universal newlines* mode. Lines may be terminated by any of *'\\n'*, the Unix end-of-line convention, *'\\r'*, the old Macintosh convention or *'\\r\\n'*, the Windows convention. All of these external representations are seen as *'\\n'* by the Python program.

Note: This feature is only available if Python is built with universal newline support (the default). Also, the *newlines* attribute of the file objects *stdout*, *stdin* and *stderr* are not updated by the *communicate()* method.

If given, *startupinfo* will be a *STARTUPINFO* object, which is passed to the underlying *CreateProcess* function. *creationflags*, if given, can be *CREATE_NEW_CONSOLE* or *CREATE_NEW_PROCESS_GROUP*. (Windows only)

Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called *child_traceback*, which is a string containing traceback information from the child's point of view.

The most common exception raised is *OSError*. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for *OSError* exceptions.

A *ValueError* will be raised if *Popen* is called with invalid arguments.

check_call() and *check_output()* will raise *CalledProcessError* if the called process returns a non-zero return code.

Security

Unlike some other *popen* functions, this implementation will never call a system shell implicitly. This means that all characters, including shell metacharacters, can safely be passed to child processes. Obviously, if the shell is invoked explicitly, then it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately.

17.1.2 Popen Objects

Instances of the *Popen* class have the following methods:

`Popen.poll()`

Check if child process has terminated. Set and return *returncode* attribute.

`Popen.wait()`

Wait for child process to terminate. Set and return *returncode* attribute.

Warning: This will deadlock when using `stdout=PIPE` and/or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use `communicate()` to avoid that.

`Popen.communicate(input=None)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional *input* argument should be a string to be sent to the child process, or `None`, if no data should be sent to the child.

`communicate()` returns a tuple (stdoutdata, stderrdata).

Note that if you want to send data to the process's stdin, you need to create the *Popen* object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

Note: The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

`Popen.send_signal(signal)`

Sends the signal *signal* to the child.

Note: On Windows, `SIGTERM` is an alias for `terminate()`. `CTRL_C_EVENT` and `CTRL_BREAK_EVENT` can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

New in version 2.6.

`Popen.terminate()`

Stop the child. On Posix OSs the method sends `SIGTERM` to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

New in version 2.6.

`Popen.kill()`

Kills the child. On Posix OSs the function sends `SIGKILL` to the child. On Windows `kill()` is an alias for `terminate()`.

New in version 2.6.

The following attributes are also available:

Warning: Use `communicate()` rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

Popen.stdin

If the *stdin* argument was *PIPE*, this attribute is a file object that provides input to the child process. Otherwise, it is *None*.

Popen.stdout

If the *stdout* argument was *PIPE*, this attribute is a file object that provides output from the child process. Otherwise, it is *None*.

Popen.stderr

If the *stderr* argument was *PIPE*, this attribute is a file object that provides error output from the child process. Otherwise, it is *None*.

Popen.pid

The process ID of the child process.

Note that if you set the *shell* argument to *True*, this is the process ID of the spawned shell.

Popen.returncode

The child return code, set by *poll()* and *wait()* (and indirectly by *communicate()*). A *None* value indicates that the process hasn't terminated yet.

A negative value *-N* indicates that the child was terminated by signal *N* (Unix only).

17.1.3 Windows Popen Helpers

The *STARTUPINFO* class and following constants are only available on Windows.

class subprocess.STARTUPINFO

Partial support of the Windows *STARTUPINFO* structure is used for *Popen* creation.

dwFlags

A bit field that determines whether certain *STARTUPINFO* attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess.STARTF_USESHOWWINDOW
```

hStdInput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard input handle for the process. If *STARTF_USESTDHANDLES* is not specified, the default for standard input is the keyboard buffer.

hStdOutput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

hStdError

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

wShowWindow

If *dwFlags* specifies *STARTF_USESHOWWINDOW*, this attribute can be any of the values that can be specified in the *nCmdShow* parameter for the *ShowWindow* function, except for *SW_SHOWDEFAULT*. Otherwise, this attribute is ignored.

SW_HIDE is provided for this attribute. It is used when *Popen* is called with *shell=True*.

Constants

The `subprocess` module exposes the following constants.

`subprocess.STD_INPUT_HANDLE`

The standard input device. Initially, this is the console input buffer, `CONIN$`.

`subprocess.STD_OUTPUT_HANDLE`

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.STD_ERROR_HANDLE`

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.SW_HIDE`

Hides the window. Another window will be activated.

`subprocess.STARTF_USESTDHANDLES`

Specifies that the `STARTUPINFO.hStdInput`, `STARTUPINFO.hStdOutput`, and `STARTUPINFO.hStdError` attributes contain additional information.

`subprocess.STARTF_USESHOWWINDOW`

Specifies that the `STARTUPINFO.wShowWindow` attribute contains additional information.

`subprocess.CREATE_NEW_CONSOLE`

The new process has a new console, instead of inheriting its parent's console (the default).

This flag is always set when `Popen` is created with `shell=True`.

`subprocess.CREATE_NEW_PROCESS_GROUP`

A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if `CREATE_NEW_CONSOLE` is specified.

17.1.4 Replacing Older Functions with the `subprocess` Module

In this section, “a becomes b” means that b can be used as a replacement for a.

Note: All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise `OSError` instead.

In addition, the replacements using `check_output()` will fail with a `CalledProcessError` if the requested operation produces a non-zero return code. The output is still available as the `output` attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the `subprocess` module.

Replacing `/bin/sh` shell backquote

```
output=`mycmd myarg`
```

becomes:

```
output = check_output(["mycmd", "myarg"])
```

Replacing shell pipeline

```
output=`dmesg | grep hda`
```

becomes:

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close() # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the `p2` is important in order for `p1` to receive a `SIGPIPE` if `p2` exits before `p1`.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```
output=`dmesg | grep hda`
```

becomes:

```
output=check_output("dmesg | grep hda", shell=True)
```

Replacing `os.system()`

```
status = os.system("mycmd" + " myarg")
# becomes
status = subprocess.call("mycmd" + " myarg", shell=True)
```

Notes:

- Calling the program through the shell is usually not required.

A more realistic example would look like this:

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print >>sys.stderr, "Child was terminated by signal", -retcode
    else:
        print >>sys.stderr, "Child returned", retcode
except OSError as e:
    print >>sys.stderr, "Execution failed:", e
```

Replacing the `os.spawn` family

`P_NOWAIT` example:

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

`P_WAIT` example:

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])
```

Vector example:

```
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

Environment example:

```
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```

Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```
pipe = os.popen("cmd", 'r', bufsize)
==>
pipe = Popen("cmd", shell=True, bufsize=bufsize, stdout=PIPE).stdout
```

```
pipe = os.popen("cmd", 'w', bufsize)
==>
pipe = Popen("cmd", shell=True, bufsize=bufsize, stdin=PIPE).stdin
```

```
(child_stdin, child_stdout) = os.popen2("cmd", mode, bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

```
(child_stdin,
 child_stdout,
 child_stderr) = os.popen3("cmd", mode, bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)
```

```
(child_stdin, child_stdout_and_stderr) = os.popen4("cmd", mode,
                                                    bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)
```

On Unix, `os.popen2`, `os.popen3` and `os.popen4` also accept a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows:

```
(child_stdin, child_stdout) = os.popen2(["/bin/ls", "-l"], mode,
                                         bufsize)
==>
p = Popen(["/bin/ls", "-l"], bufsize=bufsize, stdin=PIPE, stdout=PIPE)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

Return code handling translates as follows:

```
pipe = os.popen("cmd", 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print "There were some errors"
==>
process = Popen("cmd", shell=True, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print "There were some errors"
```

Replacing functions from the `popen2` module

```
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize, mode)
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
         stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

On Unix, `popen2` also accepts a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows:

```
(child_stdout, child_stdin) = popen2.popen2(["mycmd", "myarg"], bufsize,
                                             mode)
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
         stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

`popen2.Popen3` and `popen2.Popen4` basically work as `subprocess.Popen`, except that:

- `Popen` raises an exception if the execution fails.
- the `capturestderr` argument is replaced with the `stderr` argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
- `popen2` closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen`.

17.1.5 Notes

Converting an argument sequence to a string on Windows

On Windows, an `args` sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.

5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

17.2 `socket` — Low-level networking interface

This module provides access to the BSD *socket* interface. It is available on all modern Unix systems, Windows, Mac OS X, BeOS, OS/2, and probably additional platforms.

Note: Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

For an introduction to socket programming (in C), see the following papers: An Introductory 4.3BSD Interprocess Communication Tutorial, by Stuart Sechrest and An Advanced 4.3BSD Interprocess Communication Tutorial, by Samuel J. Leffler et al, both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to [RFC 3493](#) titled Basic Socket Interface Extensions for IPv6.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style: the `socket()` function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

Socket addresses are represented as follows: A single string is used for the `AF_UNIX` address family. A pair (`host`, `port`) is used for the `AF_INET` address family, where `host` is a string representing either a hostname in Internet domain notation like 'daring.cwi.nl' or an IPv4 address like '100.50.200.5', and `port` is an integer. For `AF_INET6` address family, a four-tuple (`host`, `port`, `flowinfo`, `scopeid`) is used, where `flowinfo` and `scopeid` represents `sin6_flowinfo` and `sin6_scope_id` member in `struct sockaddr_in6` in C. For `socket` module methods, `flowinfo` and `scopeid` can be omitted just for backward compatibility. Note, however, omission of `scopeid` can cause problems in manipulating scoped IPv6 addresses. Other address families are currently not supported. The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents `INADDR_ANY`, and the string '<broadcast>' represents `INADDR_BROADCAST`. The behavior is not available for IPv6 for backward compatibility, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the `host` portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in `host` portion.

New in version 2.5: `AF_NETLINK` sockets are represented as pairs `pid`, `groups`.

New in version 2.6: Linux-only support for TIPC is also available using the `AF_TIPC` address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (`addr_type`, `v1`, `v2`, `v3` [, `scope`]), where:

- `addr_type` is one of `TIPC_ADDR_NAMESEQ`, `TIPC_ADDR_NAME`, or `TIPC_ADDR_ID`.
- `scope` is one of `TIPC_ZONE_SCOPE`, `TIPC_CLUSTER_SCOPE`, and `TIPC_NODE_SCOPE`.
- If `addr_type` is `TIPC_ADDR_NAME`, then `v1` is the server type, `v2` is the port identifier, and `v3` should be 0.

If *addr_type* is `TIPC_ADDR_NAMESEQ`, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.

If *addr_type* is `TIPC_ADDR_ID`, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; errors related to socket or address semantics raise the error `socket.error`.

Non-blocking mode is supported through `setblocking()`. A generalization of this based on timeouts is supported through `settimeout()`.

The module `socket` exports the following constants and functions:

exception `socket.error`

This exception is raised for socket-related errors. The accompanying value is either a string telling what went wrong or a pair (`errno`, `string`) representing an error returned by a system call, similar to the value accompanying `os.error`. See the module `errno`, which contains names for the error codes defined by the underlying operating system.

Changed in version 2.6: `socket.error` is now a child class of `IOError`.

exception `socket.herror`

This exception is raised for address-related errors, i.e. for functions that use `h_errno` in the C API, including `gethostbyname_ex()` and `gethostbyaddr()`.

The accompanying value is a pair (`h_errno`, `string`) representing an error returned by a library call. `string` represents the description of `h_errno`, as returned by the `hstrerror()` C function.

exception `socket.gaierror`

This exception is raised for address-related errors, for `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair (`error`, `string`) representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror()` C function. The `error` value will match one of the `EAI_*` constants defined in this module.

exception `socket.timeout`

This exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()`. The accompanying value is a string whose value is currently always “timed out”.

New in version 2.3.

`socket.AF_UNIX`

`socket.AF_INET`

`socket.AF_INET6`

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the `AF_UNIX` constant is not defined then this protocol is unsupported.

`socket.SOCK_STREAM`

`socket.SOCK_DGRAM`

`socket.SOCK_RAW`

`socket.SOCK_RDM`

`socket.SOCK_SEQPACKET`

These constants represent the socket types, used for the second argument to `socket()`. (Only `SOCK_STREAM` and `SOCK_DGRAM` appear to be generally useful.)

`SO_*`

`socket.SOMAXCONN`

`MSG_*`

`SOL_*`

`IPPROTO_*`

`IPPORT_*`

`INADDR_*`

IP_*
IPV6_*
EAI_*
AI_*
NI_*
TCP_*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the `socket` module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

SIO_*
RCVALL_*

Constants for Windows' `WSAIoctl()`. The constants are used as arguments to the `ioctl()` method of socket objects.

New in version 2.6.

TIPC_*

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

New in version 2.6.

`socket.has_ipv6`

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

New in version 2.3.

`socket.create_connection(address[, timeout[, source_address]])`

Connect to a TCP service listening on the Internet *address* (a 2-tuple (*host*, *port*)), and return the socket object. This is a higher-level function than `socket.connect()`: if *host* is a non-numeric hostname, it will try to resolve it for both `AF_INET` and `AF_INET6`, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by `getdefaulttimeout()` is used.

If supplied, *source_address* must be a 2-tuple (*host*, *port*) for the socket to bind to as its source address before connecting. If *host* or *port* are "" or 0 respectively the OS default behavior will be used.

New in version 2.6.

Changed in version 2.7: *source_address* was added.

`socket.getaddrinfo(host, port[, family[, socktype[, proto[, flags]]]])`

Translate the *host/port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as 'http', a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *socktype* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. By default, their value is 0, meaning that the full range of results is selected. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. Its default value is 0. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, socktype, proto, canonname, sockaddr)
```

In these tuples, *family*, *socktype*, *proto* are all integers and are meant to be passed to the `socket()` function. *canonicalname* will be a string representing the canonical name of the *host* if `AI_CANONNAME` is part of the *flags* argument; else *canonicalname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a (address, port) 2-tuple for `AF_INET`, a (address, port, flow info, scope id) 4-tuple for `AF_INET6`), and is meant to be passed to the `socket.connect()` method.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, 0, 0, socket.IPPROTO_TCP)
[(10, 1, 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80, 0, 0)),
 (2, 1, 6, '', ('93.184.216.34', 80))]
```

New in version 2.2.

`socket.getfqdn([name])`

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by `gethostbyaddr()` is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by `gethostname()` is returned.

New in version 2.0.

`socket.gethostbyname(hostname)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostbyname_ex(hostname)`

Translate a host name to IPv4 address format, extended interface. Return a triple (*hostname*, *aliaslist*, *ipaddrlist*) where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostname()`

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

If you want to know the current machine's IP address, you may want to use `gethostbyname(gethostname())`. This operation assumes that there is a valid address-to-host mapping for the host, and the assumption does not always hold.

Note: `gethostname()` doesn't always return the fully qualified domain name; use `getfqdn()` (see above).

`socket.gethostbyaddr(ip_address)`

Return a triple (*hostname*, *aliaslist*, *ipaddrlist*) where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function `getfqdn()`. `gethostbyaddr()` supports both IPv4 and IPv6.

`socket.getnameinfo(sockaddr, flags)`

Translate a socket address *sockaddr* into a 2-tuple (*host*, *port*). Depending on the settings of *flags*, the result can contain a fully-qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

New in version 2.2.

`socket.getprotobyname(protocolname)`

Translate an Internet protocol name (for example, 'icmp') to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

`socket.getservbyname(servicename[, protocolname])`

Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

`socket.getservbyport(port[, protocolname])`

Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

`socket.socket([family[, type[, proto]]])`

Create a new socket using the given address family, socket type and protocol number. The address family should be `AF_INET` (the default), `AF_INET6` or `AF_UNIX`. The socket type should be `SOCK_STREAM` (the default), `SOCK_DGRAM` or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted in that case.

`socket.socketpair([family[, type[, proto]]])`

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the `socket()` function above. The default family is `AF_UNIX` if defined on the platform; otherwise, the default is `AF_INET`. Availability: Unix.

New in version 2.4.

`socket.fromfd(fd, family, type[, proto])`

Duplicate the file descriptor `fd` (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode. Availability: Unix.

`socket.ntohl(x)`

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.ntohs(x)`

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

`socket.htonl(x)`

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.htons(x)`

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

`socket.inet_aton(ip_string)`

Convert an IPv4 address from dotted-quad string format (for example, '123.45.67.89') to 32-bit packed binary format, as a string four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary this function returns.

`inet_aton()` also accepts strings with less than three dots; see the Unix manual page `inet(3)` for details.

If the IPv4 address string passed to this function is invalid, `socket.error` will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

`socket.inet_ntoa(packed_ip)`

Convert a 32-bit packed IPv4 address (a string four characters in length) to its standard dotted-quad string representation (for example, '123.45.67.89'). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the string passed to this function is not exactly 4 bytes in length, `socket.error` will be raised. `inet_ntoa()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

`socket.inet_pton(address_family, ip_string)`

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to `inet_aton()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the IP address string `ip_string` is invalid, `socket.error` will be raised. Note that exactly what is valid depends on both the value of `address_family` and the underlying implementation of `inet_pton()`.

Availability: Unix (maybe not all platforms).

New in version 2.3.

`socket.inet_ntop(address_family, packed_ip)`

Convert a packed IP address (a string of some number of characters) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8') `inet_ntop()` is useful when a library or network protocol returns an object of type `struct in_addr` (similar to `inet_ntoa()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the string `packed_ip` is not the correct length for the specified address family, `ValueError` will be raised. A `socket.error` is raised for errors from the call to `inet_ntop()`.

Availability: Unix (maybe not all platforms).

New in version 2.3.

`socket.getdefaulttimeout()`

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

New in version 2.3.

`socket.setdefaulttimeout(timeout)`

Set the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

New in version 2.3.

`socket.SocketType`

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

See also:

Module `SocketServer` Classes that simplify writing network servers.

Module `ssl` A TLS/SSL wrapper for socket objects.

17.2.1 Socket Objects

Socket objects have the following methods. Except for `makefile()` these correspond to Unix system calls applicable to sockets.

`socket.accept()`

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a new socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

`socket.bind(address)`

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — see above.)

Note: This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

`socket.close()`

Close the socket. All future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

Note: `close()` releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call `shutdown()` before `close()`.

`socket.connect(address)`

Connect to a remote socket at *address*. (The format of *address* depends on the address family — see above.)

Note: This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

`socket.connect_ex(address)`

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

Note: This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

`socket.fileno()`

Return the socket’s file descriptor (a small integer). This is useful with `select.select()`.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as `os.fdopen()`). Unix does not have this limitation.

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

`socket.getsockname()`

Return the socket’s own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The

format of the address returned depends on the address family — see above.)

`socket.getsockopt (level, optname[, buflen])`

Return the value of the given socket option (see the Unix man page *getsockopt(2)*). The needed symbolic constants (`SO_*` etc.) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a string. It is up to the caller to decode the contents of the buffer (see the optional built-in module *struct* for a way to decode C structures encoded as strings).

`socket.ioctl (control, option)`

Platform Windows

The *ioctl()* method is a limited interface to the `WSAIoctl` system interface. Please refer to the [Win32 documentation](#) for more information.

On other platforms, the generic *fcntl.fcntl()* and *fcntl.ioctl()* functions may be used; they accept a socket object as their first argument.

New in version 2.6.

`socket.listen (backlog)`

Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 0; the maximum value is system-dependent (usually 5), the minimum value is forced to 0.

`socket.makefile ([mode[, bufsize]])`

Return a *file object* associated with the socket. (File objects are described in [File Objects](#).) The file object does not close the socket explicitly when its *close()* method is called, but only removes its reference to the socket object, so that the socket will be closed if it is not referenced from anywhere else.

The socket must be in blocking mode (it can not have a timeout). The optional *mode* and *bufsize* arguments are interpreted the same way as by the built-in *file()* function.

Note: On Windows, the file-like object created by *makefile()* cannot be used where a file object with a file descriptor is expected, such as the stream arguments of *subprocess.Popen()*.

`socket.recv (bufsize[, flags])`

Receive data from the socket. The return value is a string representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

Note: For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

`socket.recvfrom (bufsize[, flags])`

Receive data from the socket. The return value is a pair (*string*, *address*) where *string* is a string representing the data received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

`socket.recvfrom_into (buffer[, nbytes[, flags]])`

Receive data from the socket, writing it into *buffer* instead of creating a new string. The return value is a pair (*nbytes*, *address*) where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

New in version 2.5.

`socket.recv_into(buffer[, nbytes[, flags]])`

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new string. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

New in version 2.5.

`socket.send(string[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this concept, consult the socket-howto.

`socket.sendall(string[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Unlike *send()*, this method continues to send data from *string* until either all data has been sent or an error occurs. *None* is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

`socket.sendto(string, address)`

`socket.sendto(string, flags, address)`

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for *recv()* above. Return the number of bytes sent. (The format of *address* depends on the address family — see above.)

`socket.setblocking(flag)`

Set blocking or non-blocking mode of the socket: if *flag* is 0, the socket is set to non-blocking, else to blocking mode. Initially all sockets are in blocking mode. In non-blocking mode, if a *recv()* call doesn't find any data, or if a *send()* call can't immediately dispose of the data, an *error* exception is raised; in blocking mode, the calls block until they can proceed. *s.setblocking(0)* is equivalent to *s.settimeout(0.0)*; *s.setblocking(1)* is equivalent to *s.settimeout(None)*.

`socket.settimeout(value)`

Set a timeout on blocking socket operations. The *value* argument can be a nonnegative float expressing seconds, or *None*. If a float is given, subsequent socket operations will raise a *timeout* exception if the timeout period *value* has elapsed before the operation has completed. Setting a timeout of *None* disables timeouts on socket operations. *s.settimeout(0.0)* is equivalent to *s.setblocking(0)*; *s.settimeout(None)* is equivalent to *s.setblocking(1)*.

New in version 2.3.

`socket.gettimeout()`

Return the timeout in seconds (float) associated with socket operations, or *None* if no timeout is set. This reflects the last call to *setblocking()* or *settimeout()*.

New in version 2.3.

Some notes on socket blocking and timeouts: A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are always created in blocking mode. In blocking mode, operations block until complete or the system returns an error (such as connection timed out). In non-blocking mode, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately. In timeout mode, operations fail if they cannot be completed within the timeout specified for the socket or if the system returns an error. The *setblocking()* method is simply a shorthand for certain *settimeout()* calls.

Timeout mode internally sets the socket in non-blocking mode. The blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. A consequence of this is that file objects returned by the *makefile()* method must only be used when the socket is in blocking mode; in timeout or non-blocking mode file operations that cannot be completed immediately will fail.

Note that the `connect()` operation is subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. The system network stack may return a connection timeout error of its own regardless of any Python socket timeout setting.

`socket.setsockopt(level, optname, value)`

Set the value of the given socket option (see the Unix manual page `setsockopt(2)`). The needed symbolic constants are defined in the `socket` module (`SO_*` etc.). The value can be an integer or a string representing a buffer. In the latter case it is up to the caller to ensure that the string contains the proper bits (see the optional built-in module `struct` for a way to encode C structures as strings).

`socket.shutdown(how)`

Shut down one or both halves of the connection. If `how` is `SHUT_RD`, further receives are disallowed. If `how` is `SHUT_WR`, further sends are disallowed. If `how` is `SHUT_RDWR`, further sends and receives are disallowed. Depending on the platform, shutting down one half of the connection can also close the opposite half (e.g. on Mac OS X, `shutdown(SHUT_WR)` does not allow further reads on the other end of the connection).

Note that there are no methods `read()` or `write()`; use `recv()` and `send()` without `flags` argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

`socket.family`

The socket family.

New in version 2.5.

`socket.type`

The socket type.

New in version 2.5.

`socket.proto`

The socket protocol.

New in version 2.5.

17.2.2 Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()/recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```
# Echo server program
import socket

HOST = ''          # Symbolic name meaning all available interfaces
PORT = 50007       # Arbitrary non-privileged port
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.bind((HOST, PORT))
s.listen(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
```

(continues on next page)

(continued from previous page)

```

    conn.sendall(data)
conn.close()

```

```

# Echo client program
import socket

HOST = 'daring.cwi.nl'      # The remote host
PORT = 50007                # The same port as used by the server
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.connect((HOST, PORT))
s.sendall('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)

```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```

# Echo server program
import socket
import sys

HOST = None                  # Symbolic name meaning all available interfaces
PORT = 50007                 # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                              socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error as msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except socket.error as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()

```

```

# Echo client program
import socket

```

(continues on next page)

(continued from previous page)

```

import sys

HOST = 'daring.cwi.nl'      # The remote host
PORT = 50007                # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except socket.error as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
s.sendall('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)

```

The last example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```

import socket

# the public network interface
HOST = socket.gethostname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print s.recvfrom(65565)

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)

```

Running an example several times with too small delay between executions, could lead to this error:

```
socket.error: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a `socket` flag to set, in order to prevent this, `socket.SO_REUSEADDR`:

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the `SO_REUSEADDR` flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

17.3 `ssl` — TLS/SSL wrapper for socket objects

New in version 2.6.

Source code: [Lib/ssl.py](#)

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

Changed in version 2.7.13: Updated to support linking with OpenSSL 1.1.0

Note: Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

Warning: Don’t use this module without reading the [Security considerations](#). Doing so may lead to a false sense of security, as the default settings of the `ssl` module are not necessarily appropriate for your application.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, `ssl.SSLSocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as `getpeercert()`, which retrieves the certificate of the other side of the connection, and `cipher()`, which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the `ssl.SSLContext` class helps manage settings and certificates, which can then be inherited by SSL sockets created through the `SSLContext.wrap_socket()` method.

17.3.1 Functions, Constants, and Exceptions

exception `ssl.SSLError`

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption and authentication layer that’s superimposed on the underlying network connection. This error is a subtype of `socket.error`, which in turn is a subtype of `IOError`. The error code and message of `SSLError` instances are provided by the OpenSSL library.

library

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as `SSL`, `PEM` or `X509`. The range of possible values depends on the OpenSSL version.

New in version 2.7.9.

reason

A string mnemonic designating the reason this error occurred, for example `CERTIFICATE_VERIFY_FAILED`. The range of possible values depends on the OpenSSL version.

New in version 2.7.9.

exception `ssl.SSLZeroReturnError`

A subclass of `SSLError` raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn't mean that the underlying transport (read TCP) has been closed.

New in version 2.7.9.

exception `ssl.SSLWantReadError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

New in version 2.7.9.

exception `ssl.SSLWantWriteError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

New in version 2.7.9.

exception `ssl.SSLSyscallError`

A subclass of `SSLError` raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original errno number.

New in version 2.7.9.

exception `ssl.SSLEOFError`

A subclass of `SSLError` raised when the SSL connection has been terminated abruptly. Generally, you shouldn't try to reuse the underlying transport when this error is encountered.

New in version 2.7.9.

exception `ssl.CertificateError`

Raised to signal an error with a certificate (such as mismatching hostname). Certificate errors detected by OpenSSL, though, raise an `SSLError`.

Socket creation

The following function allows for standalone socket creation. Starting from Python 2.7.9, it can be more flexible to use `SSLContext.wrap_socket()` instead.

```
ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE,
                ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True,
                suppress_ragged_eofs=True, ciphers=None)
```

Takes an instance `sock` of `socket.socket`, and returns an instance of `ssl.SSLSocket`, a subtype of `socket.socket`, which wraps the underlying socket in an SSL context. `sock` must be a `SOCK_STREAM` socket; other socket types are unsupported.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after `connect()` is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the `accept()` method. `wrap_socket()` may raise `SSLError`.

The `keyfile` and `certfile` parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of [Certificates](#) for more information on how the certificate is stored in the `certfile`.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values `CERT_NONE` (certificates ignored), `CERT_OPTIONAL` (not required, but validated if provided), or `CERT_REQUIRED` (required and validated). If the value of this parameter is not `CERT_NONE`, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of [Certificates](#) for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server’s choice. Most of the versions are not interoperable with the other versions. If not specified, the default is `PROTOCOL_SSLv23`; it provides the most compatibility with other versions.

Here’s a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

| <i>client / server</i> | SSLv2 | SSLv3 | SSLv23 | TLSv1 | TLSv1.1 | TLSv1.2 |
|---------------------------|-------|-------|--------|-------|---------|---------|
| <i>SSLv2</i> | yes | no | yes | no | no | no |
| <i>SSLv3</i> | no | yes | yes | no | no | no |
| <i>SSLv23¹</i> | no | yes | yes | yes | yes | yes |
| <i>TLSv1</i> | no | no | yes | yes | no | no |
| <i>TLSv1.1</i> | no | no | yes | no | yes | no |
| <i>TLSv1.2</i> | no | no | yes | no | no | yes |

Note: Which connections succeed will vary depending on the version of OpenSSL. For example, before OpenSSL 1.0.0, an SSLv23 client would always attempt SSLv2 connections.

The `ciphers` parameter sets the available ciphers for this SSL object. It should be a string in the [OpenSSL cipher list format](#).

The parameter `do_handshake_on_connect` specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the `SSLSocket.do_handshake()` method. Calling `SSLSocket.do_handshake()` explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the `SSLSocket.read()` method should signal unexpected EOF from the other end of the connection. If specified as `True` (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if `False`, it will raise the exceptions back to the caller.

Changed in version 2.7: New optional argument `ciphers`.

Context creation

A convenience function helps create `SSLContext` objects for common purposes.

¹ TLS 1.3 protocol will be available with `PROTOCOL_SSLv23` in OpenSSL \geq 1.1.1. There is no dedicated `PROTOCOL` constant for just TLS 1.3.

`ssl.create_default_context` (*purpose*=`Purpose.SERVER_AUTH`, *cafile*=`None`, *capath*=`None`, *cadata*=`None`)

Return a new `SSLContext` object with default settings for the given *purpose*. The settings are chosen by the `ssl` module, and usually represent a higher security level than when calling the `SSLContext` constructor directly.

cafile, *capath*, *cadata* represent optional CA certificates to trust for certificate verification, as in `SSLContext.load_verify_locations()`. If all three are `None`, this function can choose to trust the system's default CA certificates instead.

The settings are: `PROTOCOL_SSLv23`, `OP_NO_SSLv2`, and `OP_NO_SSLv3` with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing `SERVER_AUTH` as *purpose* sets *verify_mode* to `CERT_REQUIRED` and either loads CA certificates (when at least one of *cafile*, *capath* or *cadata* is given) or uses `SSLContext.load_default_certs()` to load default CA certificates.

Note: The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should create a `SSLContext` and apply the settings yourself.

Note: If you find that when certain older clients or servers attempt to connect with a `SSLContext` created by this function that they get an error stating “Protocol or cipher suite mismatch”, it may be that they only support SSL3.0 which this function excludes using the `OP_NO_SSLv3`. SSL3.0 is widely considered to be **completely broken**. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```
ctx = ssl.create_default_context(Purpose.CLIENT_AUTH)
ctx.options &= ~ssl.OP_NO_SSLv3
```

New in version 2.7.9.

Changed in version 2.7.10: RC4 was dropped from the default cipher string.

Changed in version 2.7.13: ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

`ssl._https_verify_certificates` (*enable*=`True`)

Specifies whether or not server certificates are verified when creating client HTTPS connections without specifying a particular SSL context.

Starting with Python 2.7.9, `httplib` and modules which use it, such as `urllib2` and `xmllib`, default to verifying remote server certificates received when establishing client HTTPS connections. This default verification checks that the certificate is signed by a Certificate Authority in the system trust store and that the Common Name (or Subject Alternate Name) on the presented certificate matches the requested host.

Setting *enable* to `True` ensures this default behaviour is in effect.

Setting *enable* to `False` reverts the default HTTPS certificate handling to that of Python 2.7.8 and earlier, allowing connections to servers using self-signed certificates, servers using certificates signed by a Certificate Authority not present in the system trust store, and servers where the hostname does not match the presented server certificate.

The leading underscore on this function denotes that it intentionally does not exist in any implementation of Python 3 and may not be present in all Python 2.7 implementations. The portable approach to bypassing certificate checks or the system trust store when necessary is for tools to enable that on a case-by-case basis by explicitly passing in a suitably configured SSL context, rather than reverting the default behaviour of the standard library client modules.

New in version 2.7.12.

Random generation

Deprecated since version 2.7.13: OpenSSL has deprecated `ssl.RAND_pseudo_bytes()`, use `ssl.RAND_bytes()` instead.

`ssl.RAND_status()`

Return `True` if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and `False` otherwise. You can use `ssl.RAND_egd()` and `ssl.RAND_add()` to increase the randomness of the pseudo-random number generator.

`ssl.RAND_egd(path)`

If you are running an entropy-gathering daemon (EGD) somewhere, and *path* is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

See <http://egd.sourceforge.net/> or <http://prngd.sourceforge.net/> for sources of entropy-gathering daemons.

Availability: not available with LibreSSL and OpenSSL > 1.1.0

`ssl.RAND_add(bytes, entropy)`

Mix the given *bytes* into the SSL pseudo-random number generator. The parameter *entropy* (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See [RFC 1750](#) for more information on sources of entropy.

Certificate handling**`ssl.match_hostname(cert, hostname)`**

Verify that *cert* (in decoded format as returned by `SSLSocket.getpeercert()`) matches the given *hostname*. The rules applied are those for checking the identity of HTTPS servers as outlined in [RFC 2818](#) and [RFC 6125](#), except that IP addresses are not currently supported. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPs and others.

`CertificateError` is raised on failure. On success, the function returns nothing:

```
>>> cert = {'subject': (('commonName', 'example.com'),),)}
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

New in version 2.7.9.

`ssl.cert_time_to_seconds(cert_time)`

Return the time in seconds since the Epoch, given the *cert_time* string representing the “notBefore” or “notAfter” date from a certificate in “%b %d %H:%M:%S %Y %Z” strptime format (C locale).

Here’s an example:

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

“notBefore” or “notAfter” dates must use GMT ([RFC 5280](#)).

Changed in version 2.7.9: Interpret the input time as a time in UTC as specified by ‘GMT’ timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

`ssl.get_server_certificate(addr, ssl_version=PROTOCOL_SSLv23, ca_certs=None)`

Given the address `addr` of an SSL-protected server, as a (*hostname*, *port-number*) pair, fetches the server’s certificate, and returns it as a PEM-encoded string. If `ssl_version` is specified, uses that version of the SSL protocol to attempt to connect to the server. If `ca_certs` is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in `wrap_socket()`. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

Changed in version 2.7.9: This function is now IPv6-compatible, and the default `ssl_version` is changed from `PROTOCOL_SSLv3` to `PROTOCOL_SSLv23` for maximum compatibility with modern servers.

`ssl.DER_cert_to_PEM_cert(DER_cert_bytes)`

Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

`ssl.PEM_cert_to_DER_cert(PEM_cert_string)`

Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

`ssl.get_default_verify_paths()`

Returns a named tuple with paths to OpenSSL’s default cafile and capath. The paths are the same as used by `SSLContext.set_default_verify_paths()`. The return value is a *named tuple* `DefaultVerifyPaths`:

- `cafile` - resolved path to cafile or `None` if the file doesn’t exist,
- `capath` - resolved path to capath or `None` if the directory doesn’t exist,
- `openssl_cafile_env` - OpenSSL’s environment key that points to a cafile,
- `openssl_cafile` - hard coded path to a cafile,
- `openssl_capath_env` - OpenSSL’s environment key that points to a capath,
- `openssl_capath` - hard coded path to a capath directory

Availability: LibreSSL ignores the environment vars `openssl_cafile_env` and `openssl_capath_env`

New in version 2.7.9.

`ssl.enum_certificates(store_name)`

Retrieve certificates from Windows’ system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (`cert_bytes`, `encoding_type`, `trust`) tuples. The `encoding_type` specifies the encoding of `cert_bytes`. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. `trust` specifies the purpose of the certificate as a set of OIDs or exactly `True` if the certificate is trustworthy for all purposes.

Example:

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

New in version 2.7.9.

`ssl.enum_crls(store_name)`

Retrieve CRLs from Windows' system cert store. *store_name* may be one of CA, ROOT or MY. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The *encoding_type* specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data.

Availability: Windows.

New in version 2.7.9.

Constants

`ssl.CERT_NONE`

Possible value for `SSLContext.verify_mode`, or the *cert_reqs* parameter to `wrap_socket()`. In this mode (the default), no certificates will be required from the other side of the socket connection. If a certificate is received from the other end, no attempt to validate it is made.

See the discussion of *Security considerations* below.

`ssl.CERT_OPTIONAL`

Possible value for `SSLContext.verify_mode`, or the *cert_reqs* parameter to `wrap_socket()`. In this mode no certificates will be required from the other side of the socket connection; but if they are provided, validation will be attempted and an `SSLError` will be raised on failure.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the *ca_certs* parameter to `wrap_socket()`.

`ssl.CERT_REQUIRED`

Possible value for `SSLContext.verify_mode`, or the *cert_reqs* parameter to `wrap_socket()`. In this mode, certificates are required from the other side of the socket connection; an `SSLError` will be raised if no certificate is provided, or if its validation fails.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the *ca_certs* parameter to `wrap_socket()`.

`ssl.VERIFY_DEFAULT`

Possible value for `SSLContext.verify_flags`. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

New in version 2.7.9.

`ssl.VERIFY_CRL_CHECK_LEAF`

Possible value for `SSLContext.verify_flags`. In this mode, only the peer cert is checked but none of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper has been loaded `SSLContext.load_verify_locations`, validation will fail.

New in version 2.7.9.

`ssl.VERIFY_CRL_CHECK_CHAIN`

Possible value for `SSLContext.verify_flags`. In this mode, CRLs of all certificates in the peer cert chain are checked.

New in version 2.7.9.

`ssl.VERIFY_X509_STRICT`

Possible value for `SSLContext.verify_flags` to disable workarounds for broken X.509 certificates.

New in version 2.7.9.

`ssl.VERIFY_X509_TRUSTED_FIRST`

Possible value for `SSLContext.verify_flags`. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

New in version 2.7.10.

`ssl.PROTOCOL_TLS`

Selects the highest protocol version that both the client and server support. Despite the name, this option can select “TLS” protocols as well as “SSL”.

New in version 2.7.13.

`ssl.PROTOCOL_SSLv23`

Alias for `PROTOCOL_TLS`.

Deprecated since version 2.7.13: Use `PROTOCOL_TLS` instead.

`ssl.PROTOCOL_SSLv2`

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

Warning: SSL version 2 is insecure. Its use is highly discouraged.

Deprecated since version 2.7.13: OpenSSL has removed support for SSLv2.

`ssl.PROTOCOL_SSLv3`

Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the `OPENSSL_NO_SSLv3` flag.

Warning: SSL version 3 is insecure. Its use is highly discouraged.

Deprecated since version 2.7.13: OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

`ssl.PROTOCOL_TLSv1`

Selects TLS version 1.0 as the channel encryption protocol.

Deprecated since version 2.7.13: OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

`ssl.PROTOCOL_TLSv1_1`

Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

New in version 2.7.9.

Deprecated since version 2.7.13: OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

`ssl.PROTOCOL_TLSv1_2`

Selects TLS version 1.2 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

New in version 2.7.9.

Deprecated since version 2.7.13: OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

`ssl.OP_ALL`

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's `SSL_OP_ALL` constant.

New in version 2.7.9.

`ssl.OP_NO_SSLv2`

Prevents an SSLv2 connection. This option is only applicable in conjunction with `PROTOCOL_SSLv23`. It prevents the peers from choosing SSLv2 as the protocol version.

New in version 2.7.9.

`ssl.OP_NO_SSLv3`

Prevents an SSLv3 connection. This option is only applicable in conjunction with `PROTOCOL_SSLv23`. It prevents the peers from choosing SSLv3 as the protocol version.

New in version 2.7.9.

`ssl.OP_NO_TLSv1`

Prevents a TLSv1 connection. This option is only applicable in conjunction with `PROTOCOL_SSLv23`. It prevents the peers from choosing TLSv1 as the protocol version.

New in version 2.7.9.

`ssl.OP_NO_TLSv1_1`

Prevents a TLSv1.1 connection. This option is only applicable in conjunction with `PROTOCOL_SSLv23`. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

New in version 2.7.9.

`ssl.OP_NO_TLSv1_2`

Prevents a TLSv1.2 connection. This option is only applicable in conjunction with `PROTOCOL_SSLv23`. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

New in version 2.7.9.

`ssl.OP_NO_TLSv1_3`

Prevents a TLSv1.3 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to 0.

New in version 2.7.15.

`ssl.OP_CIPHER_SERVER_PREFERENCE`

Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

New in version 2.7.9.

`ssl.OP_SINGLE_DH_USE`

Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 2.7.9.

`ssl.OP_SINGLE_ECDH_USE`

Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 2.7.9.

`ssl.OP_ENABLE_MIDDLEBOX_COMPAT`

Send dummy Change Cipher Spec (CCS) messages in TLS 1.3 handshake to make a TLS 1.3 connection look more like a TLS 1.2 connection.

This option is only available with OpenSSL 1.1.1 and later.

New in version 2.7.16.

`ssl.OP_NO_COMPRESSION`

Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

New in version 2.7.9.

`ssl.HAS_ALPN`

Whether the OpenSSL library has built-in support for the *Application-Layer Protocol Negotiation* TLS extension as described in [RFC 7301](#).

New in version 2.7.10.

`ssl.HAS_ECDH`

Whether the OpenSSL library has built-in support for Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

New in version 2.7.9.

`ssl.HAS_SNI`

Whether the OpenSSL library has built-in support for the *Server Name Indication* extension (as defined in [RFC 4366](#)).

New in version 2.7.9.

`ssl.HAS_NPN`

Whether the OpenSSL library has built-in support for *Next Protocol Negotiation* as described in the [NPN draft specification](#). When true, you can use the `SSLContext.set_npn_protocols()` method to advertise which protocols you want to support.

New in version 2.7.9.

`ssl.HAS_TLSv1_3`

Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

New in version 2.7.15.

`ssl.CHANNEL_BINDING_TYPES`

List of supported TLS channel binding types. Strings in this list can be used as arguments to `SSLSocket.get_channel_binding()`.

New in version 2.7.9.

`ssl.OPENSSL_VERSION`

The version string of the OpenSSL library loaded by the interpreter:

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 0.9.8k 25 Mar 2009'
```

New in version 2.7.

`ssl.OPENSSL_VERSION_INFO`

A tuple of five integers representing version information about the OpenSSL library:

```
>>> ssl.OPENSSL_VERSION_INFO
(0, 9, 8, 11, 15)
```

New in version 2.7.

`ssl.OPENSSL_VERSION_NUMBER`

The raw version number of the OpenSSL library, as a single integer:

```
>>> ssl.OPENSSL_VERSION_NUMBER
9470143L
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x9080bfl'
```

New in version 2.7.

`ssl.ALERT_DESCRIPTION_HANDSHAKE_FAILURE`

`ssl.ALERT_DESCRIPTION_INTERNAL_ERROR`

`ALERT_DESCRIPTION_*`

Alert Descriptions from [RFC 5246](#) and others. The [IANA TLS Alert Registry](#) contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in `SSLContext.set_servername_callback()`.

New in version 2.7.9.

Purpose. `SERVER_AUTH`

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

New in version 2.7.9.

Purpose. `CLIENT_AUTH`

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

New in version 2.7.9.

17.3.2 SSL Sockets

SSL sockets provide the following methods of *Socket Objects*:

- `accept()`
- `bind()`
- `close()`
- `connect()`
- `fileno()`
- `getpeername()`, `getsockname()`
- `getsockopt()`, `setsockopt()`
- `gettimeout()`, `settimeout()`, `setblocking()`
- `listen()`
- `makefile()`

- `recv()`, `recv_into()` (but passing a non-zero `flags` argument is not allowed)
- `send()`, `sendall()` (with the same limitation)
- `shutdown()`

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the *notes on non-blocking sockets*.

SSL sockets also have the following additional methods and attributes:

`SSLSocket.do_handshake()`

Perform the SSL setup handshake.

Changed in version 2.7.9: The handshake method also performs `match_hostname()` when the `check_hostname` attribute of the socket's `context` is true.

`SSLSocket.getpeercert(binary_form=False)`

If there is no certificate for the peer on the other end of the connection, return `None`. If the SSL handshake hasn't been done yet, raise `ValueError`.

If the `binary_form` parameter is `False`, and a certificate was received from the peer, this method returns a `dict` instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the *Subject Alternative Name* extension (see [RFC 3280](#)), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```
{'issuer': (((('countryName', 'IL'),),
              (('organizationName', 'StartCom Ltd.'),),
              (('organizationalUnitName',
                'Secure Digital Certificate Signing'),),
              (('commonName',
                'StartCom Class 2 Primary Intermediate Server CA'),)),
 'notAfter': 'Nov 22 08:15:19 2013 GMT',
 'notBefore': 'Nov 21 03:09:52 2011 GMT',
 'serialNumber': '95F0',
 'subject': (((('description', '571208-SLe257oHY9fVQ07Z'),),
               (('countryName', 'US'),),
               (('stateOrProvinceName', 'California'),),
               (('localityName', 'San Francisco'),),
               (('organizationName', 'Electronic Frontier Foundation, Inc.'),),
               (('commonName', '*.eff.org'),),
               (('emailAddress', 'hostmaster@eff.org'),)),
 'subjectAltName': (('DNS', '*.eff.org'), ('DNS', 'eff.org')),
 'version': 3}
```

Note: To validate a certificate for a particular service, you can use the `match_hostname()` function.

If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required;

- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore `getpeercert()` will return `None` if you used `CERT_NONE` (rather than `CERT_OPTIONAL` or `CERT_REQUIRED`).

Changed in version 2.7.9: The returned dictionary includes additional items such as `issuer` and `notBefore`. Additionally `ValueError` is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and OSCP URIs.

`SSLSocket.cipher()`

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

`SSLSocket.compression()`

Return the compression algorithm being used as a string, or `None` if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use `OP_NO_COMPRESSION` to disable SSL-level compression.

New in version 2.7.9.

`SSLSocket.get_channel_binding(cb_type="tls-unique")`

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The `cb_type` parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the `CHANNEL_BINDING_TYPES` list. Currently only the 'tls-unique' channel binding, defined by [RFC 5929](#), is supported. `ValueError` will be raised if an unsupported channel binding type is requested.

New in version 2.7.9.

`SSLSocket.selected_alpn_protocol()`

Return the protocol that was selected during the TLS handshake. If `SSLContext.set_alpn_protocols()` was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

New in version 2.7.10.

`SSLSocket.selected_npn_protocol()`

Return the higher-level protocol that was selected during the TLS/SSL handshake. If `SSLContext.set_npn_protocols()` was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

New in version 2.7.9.

`SSLSocket.unwrap()`

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

`SSLSocket.version()`

Return the actual SSL protocol version negotiated by the connection as a string, or `None` if no secure connection is established. As of this writing, possible return values include `"SSLv2"`, `"SSLv3"`, `"TLSv1"`, `"TLSv1.1"` and `"TLSv1.2"`. Recent OpenSSL versions may define more return values.

New in version 2.7.9.

`SSLSocket.context`

The `SSLContext` object this SSL socket is tied to. If the SSL socket was created using the top-level `wrap_socket()` function (rather than `SSLContext.wrap_socket()`), this is a custom context object created for this SSL socket.

New in version 2.7.9.

17.3.3 SSL Contexts

New in version 2.7.9.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

class `ssl.SSLContext` (*protocol*)

Create a new SSL context. You must pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. `PROTOCOL_SSLv23` is currently recommended for maximum interoperability.

See also:

`create_default_context()` lets the `ssl` module choose security settings for a given purpose.

Changed in version 2.7.16: The context is created with secure default values. The options `OP_NO_COMPRESSION`, `OP_CIPHER_SERVER_PREFERENCE`, `OP_SINGLE_DH_USE`, `OP_SINGLE_ECDH_USE`, `OP_NO_SSLv2` (except for `PROTOCOL_SSLv2`), and `OP_NO_SSLv3` (except for `PROTOCOL_SSLv3`) are set by default. The initial cipher suite list contains only HIGH ciphers, no NULL ciphers and no MD5 ciphers (except for `PROTOCOL_SSLv2`).

`SSLContext` objects have the following methods and attributes:

`SSLContext.cert_store_stats()`

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

`SSLContext.load_cert_chain` (*certfile*, *keyfile=None*, *password=None*)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from *certfile* as well. See the discussion of [Certificates](#) for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An `SSLError` is raised if the private key doesn't match with the certificate.

`SSLContext.load_default_certs` (*purpose=Purpose.SERVER_AUTH*)

Load a set of default "certification authority" (CA) certificates from default locations. On Windows it loads CA certs from the CA and ROOT system stores. On other systems it calls `SSLContext.set_default_verify_paths()`. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings `Purpose.SERVER_AUTH` loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). `Purpose.CLIENT_AUTH` loads CA certificates for client certificate verification on the server side.

`SSLContext.load_verify_locations (cafile=None, capath=None, cadata=None)`

Load a set of “certification authority” (CA) certificates used to validate other peers’ certificates when *verify_mode* is other than `CERT_NONE`. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, `SSLContext.verify_flags` must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of *Certificates* for more information about how to arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an *OpenSSL specific layout*.

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

`SSLContext.get_ca_certs (binary_form=False)`

Get a list of loaded “certification authority” (CA) certificates. If the *binary_form* parameter is `False` each list entry is a dict like the output of `SSLSocket.getpeercert()`. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from *capath* unless a certificate was requested and loaded by a SSL connection.

Note: Certificates in a *capath* directory aren’t loaded unless they have been used at least once.

`SSLContext.set_default_verify_paths ()`

Load a set of default “certification authority” (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there’s no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

`SSLContext.set_ciphers (ciphers)`

Set the available ciphers for sockets created with this context. It should be a string in the *OpenSSL cipher list format*. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an `SSLError` will be raised.

Note: when connected, the `SSLSocket.cipher()` method of SSL sockets will give the currently selected cipher.

OpenSSL 1.1.1 has TLS 1.3 cipher suites enabled by default. The suites cannot be disabled with `set_ciphers()`.

`SSLContext.set_alpn_protocols (protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to **RFC 7301**. After a successful handshake, the `SSLSocket.selected_alpn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_ALPN` is `False`.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise `SSLError` when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, `SSLSocket.selected_alpn_protocol()` returns `None`.

New in version 2.7.10.

`SSLContext.set_npn_protocols(protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the [NPN draft specification](#). After a successful handshake, the `SSLSocket.selected_npn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_NPN` is False.

`SSLContext.set_servername_callback(server_name_callback)`

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in [RFC 6066](#) section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If `server_name_callback` is `None` then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function, `server_name_callback`, will be called with three arguments; the first being the `ssl.SSLSocket`, the second is a string that represents the server name that the client is intending to communicate (or `None` if the TLS Client Hello does not contain a server name) and the third argument is the original `SSLContext`. The server name argument is the IDNA decoded server name.

A typical use of this callback is to change the `ssl.SSLSocket`'s `SSLSocket.context` attribute to a new object of type `SSLContext` representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like `SSLSocket.selected_alpn_protocol()` and `SSLSocket.context`. `SSLSocket.getpeercert()`, `SSLSocket.getpeername()`, `SSLSocket.cipher()` and `SSLSocket.compress()` methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The `server_name_callback` function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant `ALERT_DESCRIPTION_*` can be returned. Other return values will result in a TLS fatal error with `ALERT_DESCRIPTION_INTERNAL_ERROR`.

If there is an IDNA decoding error on the server name, the TLS connection will terminate with an `ALERT_DESCRIPTION_INTERNAL_ERROR` fatal TLS alert message to the client.

If an exception is raised from the `server_name_callback` function the TLS connection will terminate with a fatal TLS alert message `ALERT_DESCRIPTION_HANDSHAKE_FAILURE`.

This method will raise `NotImplementedError` if the OpenSSL library had `OPENSSL_NO_TLSEXT` defined when it was built.

`SSLContext.load_dh_params(dhfile)`

Load the key generation parameters for Diffie-Hellman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The `dhfile` parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_DH_USE` option to further improve security.

`SSLContext.set_ecdh_curve(curve_name)`

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The `curve_name` parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_ECDH_USE` option to further improve security.

This method is not available if `HAS_ECDH` is False.

See also:

SSL/TLS & Perfect Forward Secrecy Vincent Bernat.

`SSLContext.wrap_socket(sock, server_side=False, do_handshake_on_connect=True, suppress_ragged_eofs=True, server_hostname=None)`

Wrap an existing Python socket `sock` and return an `SSLSocket` object. `sock` must be a `SOCK_STREAM` socket; other socket types are unsupported.

The returned SSL socket is tied to the context, its settings and certificates. The parameters `server_side`, `do_handshake_on_connect` and `suppress_ragged_eofs` have the same meaning as in the top-level `wrap_socket()` function.

On client connections, the optional parameter `server_hostname` specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying `server_hostname` will raise a `ValueError` if `server_side` is true.

Changed in version 2.7.9: Always allow a `server_hostname` to be passed, even if OpenSSL does not have SNI.

`SSLContext.session_stats()`

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each [piece of information](#) to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

`SSLContext.check_hostname`

Whether to match the peer cert's hostname with `match_hostname()` in `SSLSocket.do_handshake()`. The context's `verify_mode` must be set to `CERT_OPTIONAL` or `CERT_REQUIRED`, and you must pass `server_hostname` to `wrap_socket()` in order to match the hostname.

Example:

```
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLS)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname='www.verisign.com')
ssl_sock.connect(('www.verisign.com', 443))
```

Note: This feature requires OpenSSL 0.9.8f or newer.

`SSLContext.options`

An integer representing the set of SSL options enabled on this context. The default value is `OP_ALL`, but you can specify other options such as `OP_NO_SSLv2` by ORing them together.

Note: With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a `ValueError`.

SSLContext.protocol

The protocol version chosen when constructing the context. This attribute is read-only.

SSLContext.verify_flags

The flags for certificate verification operations. You can set flags like `VERIFY_CRL_CHECK_LEAF` by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

SSLContext.verify_mode

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of `CERT_NONE`, `CERT_OPTIONAL` or `CERT_REQUIRED`.

17.3.4 Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called "notBefore" and "notAfter".

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as "PEM" (see [RFC 1422](#)), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who "is" the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
```

(continues on next page)

(continued from previous page)

```
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling `SSLContext.load_default_certs()`, this is done automatically with `create_default_context()`.

Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to `SSLContext.load_cert_chain()` and `wrap_socket()` needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
.....++++++
.....++++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Organization, Inc.
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
```

(continues on next page)

(continued from previous page)

```
Email Address []:ops@myserver.mygroup.myorganization.com
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

17.3.5 Examples

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    ... # do something that requires SSL support
```

Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS)
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get an error and have to adjust the location)

When you use the context to connect to a server, `CERT_REQUIRED` validates the server certificate: it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness:

```
>>> conn = context.wrap_socket(socket.socket(socket.AF_INET),
...                             server_hostname="www.python.org")
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate:

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2ExtendedValidationServerCA.crt',),
 'crlDistributionPoints': ('http://crl3.digicert.com/sha2-ev-server-g1.crl',
                           'http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': (((('countryName', 'US'),),
               (('organizationName', 'DigiCert Inc'),),
               (('organizationalUnitName', 'www.digicert.com'),),
               (('commonName', 'DigiCert SHA2 Extended Validation Server CA'),)),
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': (((('businessCategory', 'Private Organization'),),
                (('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
                (('1.3.6.1.4.1.311.60.2.1.2', 'Delaware'),),
                (('serialNumber', '3359300'),),
                (('streetAddress', '16 Allen Rd'),),
                (('postalCode', '03894-4801'),),
                (('countryName', 'US'),),
                (('stateOrProvinceName', 'NH'),),
                (('localityName', 'Wolfeboro,'),),
                (('organizationName', 'Python Software Foundation'),),
                (('commonName', 'www.python.org'),)),
 'subjectAltName': (('DNS', 'www.python.org'),
                    ('DNS', 'python.org'),
                    ('DNS', 'pypi.org'),
                    ('DNS', 'docs.python.org'),
                    ('DNS', 'testpypi.python.org'),
                    ('DNS', 'bugs.python.org'),
                    ('DNS', 'wiki.python.org'),
                    ('DNS', 'hg.python.org'),
                    ('DNS', 'mail.python.org'),
                    ('DNS', 'packaging.python.org'),
                    ('DNS', 'pythonhosted.org'),
                    ('DNS', 'www.pythonhosted.org'),
                    ('DNS', 'test.pythonhosted.org'),
                    ('DNS', 'us.pycon.org'),
                    ('DNS', 'id.python.org')),
 'version': 3}
```

Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\r\n\r\n")
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
 b'Accept-Ranges: bytes',
 b'Via: 1.1 varnish',
 b'Age: 2188',
 b'X-Served-By: cache-lcy1134-LCY',
 b'X-Cache: HIT',
 b'X-Cache-Hits: 11',
```

(continues on next page)

(continued from previous page)

```
b'Vary: Cookie',
b'Strict-Transport-Security: max-age=63072000; includeSubDomains',
b'Connection: close',
b'',
b'']
```

See the discussion of *Security considerations* below.

Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call `listen()` on it, and start waiting for clients to connect:

```
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call `accept()` on the socket to get the new socket from the other end, and use the context's `SSLContext.wrap_socket()` method to create a server-side SSL socket for the connection:

```
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```
def deal_with_client(connstream):
    data = connstream.read()
    # null data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.read()
    # finished with client
```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in non-blocking mode and use an event loop).

17.3.6 Notes on non-blocking sockets

When working with non-blocking sockets, there are several things you need to be aware of:

- Calling `select()` tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to `select()`.
- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without `select()` being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and then only block on a `select()` call if still necessary.

(of course, similar provisions apply when using other primitives such as `poll()`, or those in the `selectors` module)

- The SSL handshake itself will be non-blocking: the `SSLSocket.do_handshake()` method has to be retried until it returns successfully. Here is a synopsis using `select()` to wait for the socket's readiness:

```
while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
        select.select([sock], [], [])
    except ssl.SSLWantWriteError:
        select.select([], [sock], [])
```

17.3.7 Security considerations

Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system's trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

If a client certificate is needed for the connection, it can be added with `SSLContext.load_cert_chain()`.

By contrast, if you create the SSL context by calling the `SSLContext` constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

Manual settings

Verifying certificates

When calling the `SSLContext` constructor directly, `CERT_NONE` is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use `CERT_REQUIRED`. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling `SSLSocket.getpeercert()`, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the `match_hostname()` function can be used. This common check is automatically performed when `SSLContext.check_hostname` is enabled.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify `CERT_REQUIRED` and similarly check the client certificate.

Note: In client mode, `CERT_OPTIONAL` and `CERT_REQUIRED` are equivalent unless anonymous ciphers are enabled (they are disabled by default).

Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use `PROTOCOL_SSLv23` as the protocol version and then disable SSLv2 and SSLv3 explicitly using the `SSLContext.options` attribute:

```
context = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
context.options |= ssl.OP_NO_SSLv2
context.options |= ssl.OP_NO_SSLv3
```

The SSL context created above will only allow TLSv1 and later (if supported by your system) connections.

Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the `SSLContext.set_ciphers()` method. Starting from Python 2.7.9, the `ssl` module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the [cipher list format](#). If you want to check which ciphers are enabled by a given cipher list, use the `openssl ciphers` command on your system.

Multi-processing

If using this module as part of a multi-processed application (using, for example the `multiprocessing` or `concurrent.futures` modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with `os.fork()`. Any successful call of `RAND_add()`, `RAND_bytes()` or `RAND_pseudo_bytes()` is sufficient.

17.3.8 LibreSSL support

LibreSSL is a fork of OpenSSL 1.0.1. The `ssl` module has limited support for LibreSSL. Some features are not available when the `ssl` module is compiled with LibreSSL.

- LibreSSL >= 2.6.1 no longer supports NPN. The methods `SSLContext.set_npn_protocols()` and `SSLSocket.selected_npn_protocol()` are not available.
- `SSLContext.set_default_verify_paths()` ignores the env vars `SSL_CERT_FILE` and `SSL_CERT_PATH` although `get_default_verify_paths()` still reports them.

17.4 `signal` — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python. Some general rules for working with signals and their handlers:

- A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.
- There is no way to “block” signals temporarily from critical sections (since this is not supported by all Unix flavors).
- Although Python signal handlers are called asynchronously as far as the Python user is concerned, they can only occur between the “atomic” instructions of the Python interpreter. This means that signals arriving during long calculations implemented purely in C (such as regular expression matches on large bodies of text) may be delayed for an arbitrary amount of time.
- When a signal arrives during an I/O operation, it is possible that the I/O operation raises an exception after the signal handler returns. This is dependent on the underlying Unix system’s semantics regarding interrupted system calls.
- Because the C signal handler always returns, it makes little sense to catch synchronous errors like `SIGFPE` or `SIGSEGV`.
- Python installs a small number of signal handlers by default: `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a `KeyboardInterrupt` exception. All of these can be overridden.
- Some care must be taken if both signals and threads are used in the same program. The fundamental thing to remember in using signals and threads simultaneously is: always perform `signal()` operations in the main thread of execution. Any thread can perform an `alarm()`, `getsignal()`, `pause()`, `setitimer()` or `getitimer()`; only the main thread can set a new signal handler, and the main thread will be the only one to receive signals (this is enforced by the Python `signal` module, even if the underlying thread implementation supports sending signals to individual threads). This means that signals can’t be used as a means of inter-thread communication. Use locks instead.

The variables defined in the `signal` module are:

`signal.SIG_DFL`

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for `SIGQUIT` is to dump core and exit, while the default action for `SIGCHLD` is to simply ignore it.

`signal.SIG_IGN`

This is another standard signal handler, which will simply ignore the given signal.

SIG*

All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for `'signal()'` lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

`signal.CTRL_C_EVENT`

The signal corresponding to the Ctrl+C keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

New in version 2.7.

`signal.CTRL_BREAK_EVENT`

The signal corresponding to the Ctrl+Break keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

New in version 2.7.

`signal.NSIG`

One more than the number of the highest signal number.

`signal.ITIMER_REAL`

Decrements interval timer in real time, and delivers SIGALRM upon expiration.

`signal.ITIMER_VIRTUAL`

Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

`signal.ITIMER_PROF`

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

The `signal` module defines one exception:

exception `signal.ItimerError`

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `IOError`.

The `signal` module defines the following functions:

`signal.alarm(time)`

If `time` is non-zero, this function requests that a SIGALRM signal be sent to the process in `time` seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If `time` is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page `alarm(2)`.) Availability: Unix.

`signal.getsignal(signalnum)`

Return the current signal handler for the signal `signalnum`. The returned value may be a callable Python object, or one of the special values `signal.SIG_IGN`, `signal.SIG_DFL` or `None`. Here, `signal.SIG_IGN` means that the signal was previously ignored, `signal.SIG_DFL` means that the default way of handling the signal was previously in use, and `None` means that the previous signal handler was not installed from Python.

`signal.pause()`

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page `signal(2)`.)

`signal.setitimer(which, seconds[, interval])`

Sets given interval timer (one of `signal.ITIMER_REAL`, `signal.ITIMER_VIRTUAL` or `signal.ITIMER_PROF`) specified by *which* to fire after *seconds* (float is accepted, different from `alarm()`) and after that every *interval* seconds. The interval timer specified by *which* can be cleared by setting seconds to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; `signal.ITIMER_REAL` will deliver `SIGALRM`, `signal.ITIMER_VIRTUAL` sends `SIGVTALRM`, and `signal.ITIMER_PROF` will deliver `SIGPROF`.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an `ItimerError`. Availability: Unix.

New in version 2.6.

`signal.getitimer(which)`

Returns current value of a given interval timer specified by *which*. Availability: Unix.

New in version 2.6.

`signal.set_wakeup_fd(fd)`

Set the wakeup fd to *fd*. When a signal is received, a '\0' byte is written to the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

New in version 2.6.

`signal.siginterrupt(signalnum, flag)`

Change system call restart behaviour: if *flag* is `False`, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true *flag* value for the given signal.

New in version 2.6.

`signal.signal(signalnum, handler)`

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values `signal.SIG_IGN` or `signal.SIG_DFL`. The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The *handler* is called with two arguments: the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the `inspect` module).

On Windows, `signal()` can only be called with `SIGABRT`, `SIGFPE`, `SIGILL`, `SIGINT`, `SIGSEGV`, or `SIGTERM`. A `ValueError` will be raised in any other case.

17.4.1 Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```
import signal, os

def handler(signum, frame):
    print 'Signal handler called with signal', signum
    raise IOError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)          # Disable the alarm
```

17.5 popen2 — Subprocesses with accessible I/O streams

Deprecated since version 2.6: This module is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

This module allows you to spawn processes and connect to their input/output/error pipes and obtain their return codes under Unix and Windows.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results. Using the `subprocess` module is preferable to using the `popen2` module.

The primary interface offered by this module is a trio of factory functions. For each of these, if *bufsize* is specified, it specifies the buffer size for the I/O pipes. *mode*, if provided, should be the string 'b' or 't'; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for *mode* is 't'.

On Unix, *cmd* may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If *cmd* is a string it will be passed to the shell (as with `os.system()`).

The only way to retrieve the return codes for the child processes is by using the `poll()` or `wait()` methods on the `Popen3` and `Popen4` classes; these are only available on Unix. This information is not available when using the `popen2()`, `popen3()`, and `popen4()` functions, or the equivalent functions in the `os` module. (Note that the tuples returned by the `os` module's functions are in a different order from the ones returned by the `popen2` module.)

`popen2.popen2(cmd[, bufsize[, mode]])`

Executes *cmd* as a sub-process. Returns the file objects (*child_stdout*, *child_stdin*).

`popen2.popen3(cmd[, bufsize[, mode]])`

Executes *cmd* as a sub-process. Returns the file objects (*child_stdout*, *child_stdin*, *child_stderr*).

`popen2.popen4(cmd[, bufsize[, mode]])`

Executes *cmd* as a sub-process. Returns the file objects (*child_stdout_and_stderr*, *child_stdin*).

New in version 2.0.

On Unix, a class defining the objects returned by the factory functions is also available. These are not used for the Windows implementation, and are not available on that platform.

class `popen2.Popen3` (*cmd* [, *capturestderr* [, *bufsize*]])

This class represents a child process. Normally, *Popen3* instances are created using the *popen2()* and *popen3()* factory functions described above.

If not using one of the helper functions to create *Popen3* objects, the parameter *cmd* is the shell command to execute in a sub-process. The *capturestderr* flag, if true, specifies that the object should capture standard error output of the child process. The default is false. If the *bufsize* parameter is specified, it specifies the size of the I/O buffers to/from the child process.

class `popen2.Popen4` (*cmd* [, *bufsize*])

Similar to *Popen3*, but always captures standard error into the same file object as standard output. These are typically created using *popen4()*.

New in version 2.0.

17.5.1 Popen3 and Popen4 Objects

Instances of the *Popen3* and *Popen4* classes have the following methods:

Popen3.**poll** ()

Returns -1 if child process hasn't completed yet, or its status code (see *wait()*) otherwise.

Popen3.**wait** ()

Waits for and returns the status code of the child process. The status code encodes both the return code of the process and information about whether it exited using the *exit()* system call or died due to a signal. Functions to help interpret the status code are defined in the *os* module; see section *Process Management* for the *W** () family of functions.

The following attributes are also available:

Popen3.**fromchild**

A file object that provides output from the child process. For *Popen4* instances, this will provide both the standard output and standard error streams.

Popen3.**tochild**

A file object that provides input to the child process.

Popen3.**childerr**

A file object that provides error output from the child process, if *capturestderr* was true for the constructor, otherwise None. This will always be None for *Popen4* instances.

Popen3.**pid**

The process ID of the child process.

17.5.2 Flow Control Issues

Any time you are working with any form of inter-process communication, control flow needs to be carefully thought out. This remains the case with the file objects provided by this module (or the *os* module equivalents).

When reading output from a child process that writes a lot of data to standard error while the parent is reading from the child's standard output, a deadlock can occur. A similar situation can occur with other combinations of reads and writes. The essential factors are that more than `_PC_PIPE_BUF` bytes are being written by one process in a blocking fashion, while the other process is reading from the first process, also in a blocking fashion.

There are several ways to deal with this situation.

The simplest application change, in many cases, will be to follow this model in the parent process:

```
import popen2

r, w, e = popen2.popen3('python slave.py')
e.readlines()
r.readlines()
r.close()
e.close()
w.close()
```

with code like this in the child:

```
import os
import sys

# note that each of these print statements
# writes a single long string

print >>sys.stderr, 400 * 'this is a test\n'
os.close(sys.stderr.fileno())
print >>sys.stdout, 400 * 'this is another test\n'
```

In particular, note that `sys.stderr` must be closed after writing all data, or `readlines()` won't return. Also note that `os.close()` must be used, as `sys.stderr.close()` won't close `stderr` (otherwise assigning to `sys.stderr` will silently close it, so no further errors can be printed).

Applications which need to support a more general approach should integrate I/O over pipes with their `select()` loops, or use separate threads to read each of the individual files provided by whichever `popen*()` function or `Popen*` class was used.

Module `subprocess` Module for spawning and managing subprocesses.

17.6 `asyncore` — Asynchronous socket handler

Source code: [Lib/asyncore.py](#)

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do “more than one thing at a time.” Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the “background.” Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The `asyncore` module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For “conversational” applications and protocols the companion `asynchat` module is invaluable.

The basic idea behind both modules is to create one or more network *channels*, instances of class `asyncore.dispatcher` and `asyncchat.async_chat`. Creating the channels adds them to a global map, used by the `loop()` function if you do not provide it with your own *map*.

Once the initial channel(s) is(are) created, calling the `loop()` function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

```
asyncore.loop([timeout[, use_poll[, map[, count]]]])
```

Enter a polling loop that terminates after *count* passes or all open channels have been closed. All arguments are optional. The *count* parameter defaults to `None`, resulting in the loop terminating only when all channels have been closed. The *timeout* argument sets the timeout parameter for the appropriate `select()` or `poll()` call, measured in seconds; the default is 30 seconds. The *use_poll* parameter, if true, indicates that `poll()` should be used in preference to `select()` (the default is `False`).

The *map* parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If *map* is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `asyncchat.async_chat` and subclasses thereof) can freely be mixed in the map.

class `asyncore.dispatcher`

The `dispatcher` class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

| Event | Description |
|-------------------------------|--|
| <code>handle_connect()</code> | Implied by the first read or write event |
| <code>handle_close()</code> | Implied by a read event with no data available |
| <code>handle_accept()</code> | Implied by a read event on a listening socket |

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

handle_read()

Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

handle_write()

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

handle_expt()

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

handle_connect()

Called when the active opener's socket actually makes a connection. Might send a "welcome" banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()

Called when the socket is closed.

handle_error()

Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()

Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint.

readable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

writable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(family, type)

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the `socket` documentation for information on creating sockets.

connect(address)

As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

send(data)

Send *data* to the remote end-point of the socket.

recv(buffer_size)

Read at most *buffer_size* bytes from the socket's remote end-point. An empty string implies that the channel has been closed from the other end.

Note that `recv()` may raise `socket.error` with `EAGAIN` or `EWouldBlock`, even though `select.select()` or `select.poll()` has reported the socket ready for reading.

listen(backlog)

Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

bind(address)

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the `socket` documentation for more information.) To mark the socket as re-usable (setting the `SO_REUSEADDR` option), call the `dispatcher` object's `set_reuse_addr()` method.

accept()

Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either `None` or a pair (*conn*, *address*) where *conn* is a new socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection. When `None` is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

close()

Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class `asyncore.dispatcher_with_send`

A *dispatcher* subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use *asynchat.async_chat*.

class `asyncore.file_dispatcher`

A *file_dispatcher* takes a file descriptor or file object along with an optional map argument and wraps it for use with the `poll()` or `loop()` functions. If provided a file object or anything with a `fileno()` method, that method will be called and passed to the *file_wrapper* constructor. Availability: UNIX.

class `asyncore.file_wrapper`

A *file_wrapper* takes an integer file descriptor and calls `os.dup()` to duplicate the handle so that the original handle may be closed independently of the *file_wrapper*. This class implements sufficient methods to emulate a socket for use by the *file_dispatcher* class. Availability: UNIX.

17.6.1 `asyncore` Example basic HTTP client

Here is a very basic HTTP client that uses the *dispatcher* class to implement its socket handling:

```
import asyncore, socket

class HTTPClient(asyncore.dispatcher):

    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.connect((host, 80))
        self.buffer = 'GET %s HTTP/1.0\r\n\r\n' % path

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print self.recv(8192)

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
asyncore.loop()
```

17.6.2 `asyncore` Example basic echo server

Here is a basic echo server that uses the *dispatcher* class to accept connections and dispatches the incoming connections to a handler:

```
import asyncore
import socket
```

(continues on next page)

(continued from previous page)

```

class EchoHandler(asyncore.dispatcher_with_send):

    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):

    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accept(self):
        pair = self.accept()
        if pair is not None:
            sock, addr = pair
            print 'Incoming connection from %s' % repr(addr)
            handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()

```

17.7 asynchat — Asynchronous socket command/response handler

Source code: [Lib/asynchat.py](#)

This module builds on the *asyncore* infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. *asynchat* defines the abstract class *async_chat* that you subclass, providing implementations of the *collect_incoming_data()* and *found_terminator()* methods. It uses the same asynchronous loop as *asyncore*, and the two types of channel, *asyncore.dispatcher* and *asynchat.async_chat*, can freely be mixed in the channel map. Typically an *asyncore.dispatcher* server channel generates new *asynchat.async_chat* channel objects as it receives incoming connection requests.

class asynchat.async_chat

This class is an abstract subclass of *asyncore.dispatcher*. To make practical use of the code you must subclass *async_chat*, providing meaningful *collect_incoming_data()* and *found_terminator()* methods. The *asyncore.dispatcher* methods can be used, although not all make sense in a message/response context.

Like *asyncore.dispatcher*, *async_chat* defines a set of events that are generated by an analysis of socket conditions after a *select()* call. Once the polling loop has been started the *async_chat* object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

ac_in_buffer_size

The asynchronous input buffer size (default 4096).

ac_out_buffer_size

The asynchronous output buffer size (default 4096).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a first-in-first-out queue (fifo) of *producers*. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its `more()` method return the empty string. At this point the `async_chat` object removes the producer from the fifo and starts using the next producer, if any. When the producer fifo is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The methods are described below.

`async_chat.close_when_done()`

Pushes a `None` on to the producer fifo. When this producer is popped off the fifo it causes the channel to be closed.

`async_chat.collect_incoming_data(data)`

Called with `data` holding an arbitrary amount of received data. The default method, which must be overridden, raises a `NotImplementedError` exception.

`async_chat.discard_buffers()`

In emergencies this method will discard any data held in the input and/or output buffers and the producer fifo.

`async_chat.found_terminator()`

Called when the incoming data stream matches the termination condition set by `set_terminator()`. The default method, which must be overridden, raises a `NotImplementedError` exception. The buffered input data should be available via an instance attribute.

`async_chat.get_terminator()`

Returns the current terminator for the channel.

`async_chat.push(data)`

Pushes data on to the channel's fifo to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

`async_chat.push_with_producer(producer)`

Takes a producer object and adds it to the producer fifo associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer's data by calling its `more()` method and send the data to the remote endpoint.

`async_chat.set_terminator(term)`

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

| term | Description |
|-------------------|--|
| <i>string</i> | Will call <code>found_terminator()</code> when the string is found in the input stream |
| <i>integer</i> | Will call <code>found_terminator()</code> when the indicated number of characters have been received |
| <code>None</code> | The channel continues to collect data forever |

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.

17.7.1 asynchat - Auxiliary Classes

class `asynchat.fifo` (`[list=None]`)

A *fifo* holding data which has been pushed by the application but not yet popped for writing to the channel. A *fifo* is a list used to hold data and/or producers until they are required. If the *list* argument is provided then it should contain producers or data items to be written to the channel.

is_empty()

Returns `True` if and only if the *fifo* is empty.

first()

Returns the least-recently *push*()ed item from the *fifo*.

push(*data*)

Adds the given data (which may be a string or a producer object) to the producer *fifo*.

pop()

If the *fifo* is not empty, returns `True`, `first()`, deleting the popped item. Returns `False`, `None` for an empty *fifo*.

17.7.2 asynchat Example

The following partial example shows how HTTP requests can be read with *asynchat*. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length`: header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```
class http_request_handler(asynchat.async_chat):

    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = ""
        self.set_terminator("\r\n\r\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log

    def collect_incoming_data(self, data):
        """Buffer the data"""
        self.ibuffer.append(data)

    def found_terminator(self):

        self.handle_request()
```

INTERNET DATA HANDLING

This chapter describes modules which support handling data formats commonly used on the Internet.

18.1 `email` — An email and MIME handling package

New in version 2.2.

The `email` package is a library for managing email messages, including MIME and other [RFC 2822](#)-based message documents. It subsumes most of the functionality in several older standard modules such as `rfc822`, `mimetools`, `multifile`, and other non-standard packages such as `mimecntl`. It is specifically *not* designed to do any sending of email messages to SMTP ([RFC 2821](#)), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting in addition to [RFC 2822](#), such MIME-related RFCs as [RFC 2045](#), [RFC 2046](#), [RFC 2047](#), and [RFC 2231](#).

The primary distinguishing feature of the `email` package is that it splits the parsing and generating of email messages from the internal *object model* representation of email. Applications using the `email` package deal primarily with objects; you can add sub-objects to messages, remove sub-objects from messages, completely re-arrange the contents, etc. There is a separate parser and a separate generator which handles the transformation from flat text to the object model, and then back to flat text again. There are also handy subclasses for some common MIME object types, and a few miscellaneous utilities that help with such common tasks as extracting and parsing message field values, creating RFC-compliant dates, etc.

The following sections describe the functionality of the `email` package. The ordering follows a progression that should be common in applications: an email message is read as flat text from a file or other source, the text is parsed to produce the object structure of the email message, this structure is manipulated, and finally, the object tree is rendered back into flat text.

It is perfectly feasible to create the object structure out of whole cloth — i.e. completely from scratch. From there, a similar progression can be taken as above.

Also included are detailed specifications of all the classes and modules that the `email` package provides, the exception classes you might encounter while using the `email` package, some auxiliary utilities, and a few examples. For users of the older `mimelib` package, or previous versions of the `email` package, a section on differences and porting is provided.

Contents of the `email` package documentation:

18.1.1 `email.message`: Representing an email message

The central class in the `email` package is the `Message` class, imported from the `email.message` module. It is the base class for the `email` object model. `Message` provides the core functionality for setting and querying header fields, and for accessing message bodies.

Conceptually, a *Message* object consists of *headers* and *payloads*. Headers are [RFC 2822](#) style field names and values where the field name and value are separated by a colon. The colon is not part of either the field name or the field value.

Headers are stored and returned in case-preserving form but are matched case-insensitively. There may also be a single envelope header, also known as the *Unix-From* header or the `From_` header. The payload is either a string in the case of simple message objects or a list of *Message* objects for MIME container documents (e.g. *multipart/** and *message/rfc822*).

Message objects provide a mapping style interface for accessing the message headers, and an explicit interface for accessing both the headers and the payload. It provides convenience methods for generating a flat text representation of the message object tree, for accessing commonly used header parameters, and for recursively walking over the object tree.

Here are the methods of the *Message* class:

class email.message.**Message**

The constructor takes no arguments.

as_string ([*unixfrom*])

Return the entire message flattened as a string. When optional *unixfrom* is `True`, the envelope header is included in the returned string. *unixfrom* defaults to `False`. Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it mangles lines that begin with `From`. For more flexibility, instantiate a *Generator* instance and use its *flatten()* method directly. For example:

```
from cStringIO import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=False, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

__str__ ()

Equivalent to `as_string(unixfrom=True)`.

is_multipart ()

Return `True` if the message's payload is a list of sub-*Message* objects, otherwise return `False`. When *is_multipart()* returns `False`, the payload should be a string object.

set_unixfrom (*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string.

get_unixfrom ()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

attach (*payload*)

Add the given *payload* to the current payload, which must be `None` or a list of *Message* objects before the call. After the call, the payload will always be a list of *Message* objects. If you want to set the payload to a scalar object (e.g. a string), use *set_payload()* instead.

get_payload ([*i*, *decode*])

Return the current payload, which will be a list of *Message* objects when *is_multipart()* is `True`, or a string when *is_multipart()* is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument *i*, *get_payload()* will return the *i*-th element of the payload, counting from zero, if *is_multipart()* is `True`. An *IndexError* will be raised if *i* is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. *is_multipart()* is `False`) and *i* is given, a *TypeError* is raised.

Optional *decode* is a flag indicating whether the payload should be decoded or not, according to the *Content-Transfer-Encoding* header. When *True* and the message is not a multipart, the payload will be decoded if this header's value is *quoted-printable* or *base64*. If some other encoding is used, or *Content-Transfer-Encoding* header is missing, or if the payload has bogus base64 data, the payload is returned as-is (undecoded). If the message is a multipart and the *decode* flag is *True*, then *None* is returned. The default for *decode* is *False*.

set_payload(*payload*[, *charset*])

Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see *set_charset()* for details.

Changed in version 2.2.2: *charset* argument added.

set_charset(*charset*)

Set the character set of the payload to *charset*, which can either be a *Charset* instance (see *email.charset*), a string naming a character set, or *None*. If it is a string, it will be converted to a *Charset* instance. If *charset* is *None*, the *charset* parameter will be removed from the *Content-Type* header (the message will not be otherwise modified). Anything else will generate a *TypeError*.

If there is no existing *MIME-Version* header one will be added. If there is no existing *Content-Type* header, one will be added with a value of *text/plain*. Whether the *Content-Type* header already exists or not, its *charset* parameter will be set to *charset.output_charset*. If *charset.input_charset* and *charset.output_charset* differ, the payload will be re-encoded to the *output_charset*. If there is no existing *Content-Transfer-Encoding* header, then the payload will be transfer-encoded, if needed, using the specified *Charset*, and a header with the appropriate value will be added. If a *Content-Transfer-Encoding* header already exists, the payload is assumed to already be correctly encoded using that *Content-Transfer-Encoding* and is not modified.

The message will be assumed to be of type *text/**, with the payload either in unicode or encoded with *charset.input_charset*. It will be encoded or converted to *charset.output_charset* and transfer encoded properly, if needed, when generating the plain text representation of the message. MIME headers (*MIME-Version*, *Content-Type*, *Content-Transfer-Encoding*) will be added as needed.

New in version 2.2.2.

get_charset()

Return the *Charset* instance associated with the message's payload.

New in version 2.2.2.

The following methods implement a mapping-like interface for accessing the message's [RFC 2822](#) headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()*, but in a *Message* object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

__len__()

Return the total number of headers, including duplicates.

__contains__(*name*)

Return true if the message object has a field named *name*. Matching is done case-insensitively and *name* should not include the trailing colon. Used for the *in* operator, e.g.:

```
if 'message-id' in myMessage:
    print 'Message-ID:', myMessage['message-id']
```

__getitem__ (*name*)

Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, *None* is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant named headers.

__setitem__ (*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

__delitem__ (*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

has_key (*name*)

Return true if the message contains a header field named *name*, otherwise return false.

keys ()

Return a list of all the message's header field names.

values ()

Return a list of all the message's field values.

items ()

Return a list of 2-tuples containing all the message's field headers and values.

get (*name*[, *failobj*])

Return the value of the named header field. This is identical to *__getitem__()* except that optional *failobj* is returned if the named header is missing (defaults to *None*).

Here are some additional useful methods:

get_all (*name*[, *failobj*])

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to *None*).

add_header (*_name*, *_value*, ***_params*)

Extended header setting. This method is similar to *__setitem__()* except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as *key="value"* unless the value is *None*, in which case only the key will be added. If the value contains non-ASCII characters, it must be specified as a three tuple in the format (*CHARSET*, *LANGUAGE*, *VALUE*), where *CHARSET* is a string naming the charset to be used to encode the value, *LANGUAGE* can usually be set to *None* or the empty string (see [RFC 2231](#) for other possibilities), and *VALUE* is the string value containing non-ASCII code points.

Here's an example:

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1'Fu%DFballer.ppt"
```

replace_header (*_name*, *_value*)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case. If no matching header was found, a *KeyError* is raised.

New in version 2.2.2.

get_content_type ()

Return the message's content type. The returned string is coerced to lower case of the form *maintype/subtype*. If there was no *Content-Type* header in the message the default type as given by *get_default_type()* will be returned. Since according to **RFC 2045**, messages always have a default type, *get_content_type()* will always return a value.

RFC 2045 defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.

New in version 2.2.2.

get_content_maintype ()

Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

New in version 2.2.2.

get_content_subtype ()

Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

New in version 2.2.2.

get_default_type ()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

New in version 2.2.2.

set_default_type (*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

New in version 2.2.2.

get_params ([*failobj* [, *header* [, *unquote*]]])

Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '=' sign. The left hand side of the '=' is the key, while the right hand side is the value. If there is no '=' sign in the parameter the value is the empty string, otherwise the value is as described in *get_param()* and is unquoted if optional *unquote* is True (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

Changed in version 2.2.2: *unquote* argument added.

get_param (*param*[, *failobj*[, *header*[, *unquote*]]])

Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to `None`).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was [RFC 2231](#) encoded. When it's a 3-tuple, the elements of the value are of the form (`CHARSET`, `LANGUAGE`, `VALUE`). Note that both `CHARSET` and `LANGUAGE` can be `None`, in which case you should consider `VALUE` to be encoded in the `us-ascii` charset. You can usually ignore `LANGUAGE`.

If your application doesn't care whether the parameter was encoded as in [RFC 2231](#), you can collapse the parameter value by calling `email.utils.collapse_rfc2231_value()`, passing in the return value from `get_param()`. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn't. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the `VALUE` item in the 3-tuple) is always unquoted, unless *unquote* is set to `False`.

Changed in version 2.2.2: *unquote* argument added, and 3-tuple return value possible.

set_param (*param*, *value*[, *header*[, *requote*[, *charset*[, *language*]]]])

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, its value will be replaced with *value*. If the *Content-Type* header has not yet been defined for this message, it will be set to `text/plain` and the new parameter value will be appended as per [RFC 2045](#).

Optional *header* specifies an alternative header to *Content-Type*, and all parameters will be quoted as necessary unless optional *requote* is `False` (the default is `True`).

If optional *charset* is specified, the parameter will be encoded according to [RFC 2231](#). Optional *language* specifies the RFC 2231 language, defaulting to the empty string. Both *charset* and *language* should be strings.

New in version 2.2.2.

del_param (*param*[, *header*[, *requote*]])

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless *requote* is `False` (the default is `True`). Optional *header* specifies an alternative to *Content-Type*.

New in version 2.2.2.

set_type (*type*[, *header*[, *requote*]])

Set the main type and subtype for the *Content-Type* header. *type* must be a string in the form `maintype/subtype`, otherwise a `ValueError` is raised.

This method replaces the *Content-Type* header, keeping all the parameters in place. If *requote* is `False`, this leaves the existing header's quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the *header* argument. When the *Content-Type* header is set a *MIME-Version* header is also added.

New in version 2.2.2.

get_filename ([*failobj*])

Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per `email.utils.unquote()`.

get_boundary ([*failobj*])

Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per `email.utils.unquote()`.

set_boundary (*boundary*)

Set the `boundary` parameter of the *Content-Type* header to *boundary*. `set_boundary()` will always quote *boundary* if necessary. A `HeaderParseError` is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via `add_header()`, because `set_boundary()` preserves the order of the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

get_content_charset ([*failobj*])

Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

Note that this method differs from `get_charset()` which returns the `Charset` instance for the default encoding of the message body.

New in version 2.2.2.

get_charsets ([*failobj*])

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

walk ()

The `walk()` method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use `walk()` as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print part.get_content_type()
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
```

Changed in version 2.5: The previously deprecated methods `get_type()`, `get_main_type()`, and `get_subtype()` were removed.

`Message` objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be *None*.

epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

Changed in version 2.5: You do not need to set the epilogue to the empty string in order for the *Generator* to print a newline at the end of the file.

defects

The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

New in version 2.4.

18.1.2 email.parser: Parsing email messages

Message object structures can be created in one of two ways: they can be created from whole cloth by instantiating *Message* objects and stringing them together via *attach()* and *set_payload()* calls, or they can be created by parsing a flat text representation of the email message.

The *email* package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a string or a file object, and the parser will return to you the root *Message* instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return *True* from its *is_multipart()* method, and the subparts can be accessed via the *get_payload()* and *walk()* methods.

There are actually two parser interfaces available for use, the classic *Parser* API and the incremental *FeedParser* API. The classic *Parser* API is fine if you have the entire text of the message in memory as a string, or if the entire message lives in a file on the file system. *FeedParser* is more appropriate for when you're reading the message from a stream which might block waiting for more input (e.g. reading an email message from a socket). The *FeedParser* can consume and parse the message incrementally, and only returns the root object when you close the parser¹.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. There is no magical connection between the *email* package's bundled parser and the *Message* class, so your custom parser can create message object trees any way it finds necessary.

FeedParser API

New in version 2.4.

The *FeedParser*, imported from the *email.feedparser* module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can

¹ As of email package version 3.0, introduced in Python 2.4, the classic *Parser* was re-implemented in terms of the *FeedParser*, so the semantics and results are identical between the two parsers.

block (e.g. a socket). The `FeedParser` can of course be used to parse an email message fully contained in a string or a file, but the classic `Parser` API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The `FeedParser`'s API is simple; you create an instance, feed it a bunch of text until there's no more to feed it, then close the parser to retrieve the root message object. The `FeedParser` is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's `defects` attribute with a list of any problems it found in a message. See the `email.errors` module for the list of defects that it can find.

Here is the API for the `FeedParser`:

```
class email.parser.FeedParser ([_factory])
```

Create a `FeedParser` instance. Optional `_factory` is a no-argument callable that will be called whenever a new message object is needed. It defaults to the `email.message.Message` class.

```
feed (data)
```

Feed the `FeedParser` some more data. `data` should be a string containing one or more lines. The lines can be partial and the `FeedParser` will stitch such partial lines together properly. The lines in the string can have any of the common three line endings, carriage return, newline, or carriage return and newline (they can even be mixed).

```
close ()
```

Closing a `FeedParser` completes the parsing of all previously fed data, and returns the root message object. It is undefined what happens if you feed more data to a closed `FeedParser`.

Parser class API

The `Parser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a string or file. The `email.parser` module also provides a second class, called `HeaderParser` which can be used if you're only interested in the headers of the message. `HeaderParser` can be much faster in these situations, since it does not attempt to parse the message body, instead setting the payload to the raw body as a string. `HeaderParser` has the same API as the `Parser` class.

```
class email.parser.Parser ([_class])
```

The constructor for the `Parser` class takes an optional argument `_class`. This must be a callable factory (such as a function or a class), and it is used whenever a sub-message object needs to be created. It defaults to `Message` (see `email.message`). The factory will be called without arguments.

The optional `strict` flag is ignored.

Deprecated since version 2.4: Because the `Parser` class is a backward compatible API wrapper around the new-in-Python 2.4 `FeedParser`, all parsing is effectively non-strict. You should simply stop passing a `strict` flag to the `Parser` constructor.

Changed in version 2.2.2: The `strict` flag was added.

Changed in version 2.4: The `strict` flag was deprecated.

The other public `Parser` methods are:

```
parse (fp[, headersonly])
```

Read all the data from the file-like object `fp`, parse the resulting text, and return the root message object. `fp` must support both the `readline()` and the `read()` methods on file-like objects.

The text contained in `fp` must be formatted as a block of **RFC 2822** style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts).

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

Changed in version 2.2.2: The *headersonly* flag was added.

parsestr(*text*[, *headersonly*])

Similar to the *parse()* method, except it takes a string object instead of a file-like object. Calling this method on a string is exactly equivalent to wrapping *text* in a *StringIO* instance first and calling *parse()*.

Optional *headersonly* is as with the *parse()* method.

Changed in version 2.2.2: The *headersonly* flag was added.

Since creating a message object structure from a string or a file object is such a common task, two functions are provided as a convenience. They are available in the top-level *email* package namespace.

email.message_from_string(*s*[, *_class*[, *strict*]])

Return a message object structure from a string. This is exactly equivalent to `Parser().parsestr(s)`. Optional *_class* and *strict* are interpreted as with the *Parser* class constructor.

Changed in version 2.2.2: The *strict* flag was added.

email.message_from_file(*fp*[, *_class*[, *strict*]])

Return a message object structure tree from an open file object. This is exactly equivalent to `Parser().parse(fp)`. Optional *_class* and *strict* are interpreted as with the *Parser* class constructor.

Changed in version 2.2.2: The *strict* flag was added.

Here's an example of how you might use this at an interactive Python prompt:

```
>>> import email
>>> msg = email.message_from_string(myString)
```

Additional notes

Here are some notes on the parsing semantics:

- Most non-*multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for *is_multipart()*. Their *get_payload()* method will return a string object.
- All *multipart* type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for *is_multipart()* and their *get_payload()* method will return the list of *Message* subparts.
- Most messages with a content type of *message/** (e.g. *message/delivery-status* and *message/rfc822*) will also be parsed as container object containing a list payload of length 1. Their *is_multipart()* method will return `True`. The single element in the list payload will be a sub-message object.
- Some non-standards compliant messages may not be internally consistent about their *multipart*-edness. Such messages may have a *Content-Type* header of type *multipart*, but their *is_multipart()* method may return `False`. If such messages were parsed with the *FeedParser*, they will have an instance of the *MultipartInvariantViolationDefect* class in their *defects* attribute list. See *email.errors* for details.

18.1.3 email.generator: Generating MIME documents

One of the most common tasks is to generate the flat text of the email message represented by a message object structure. You will need to do this if you want to send your message via the *smtplib* module or the *nntplib* module, or print

the message on the console. Taking a message object structure and producing a flat text document is the job of the *Generator* class.

Again, as with the *email.parser* module, you aren't limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the transformation from flat text, to a message structure via the *Parser* class, and back to flat text, is idempotent (the input is identical to the output)¹. On the other hand, using the *Generator* on a *Message* constructed by program may result in changes to the *Message* object as defaults are filled in.

Here are the public methods of the *Generator* class, imported from the *email.generator* module:

class *email.generator.Generator* (*outfp*[, *mangle_from_*[, *maxheaderlen*]])

The constructor for the *Generator* class takes a file-like object called *outfp* for an argument. *outfp* must support the *write()* method and be usable as the output file in a Python extended print statement.

Optional *mangle_from_* is a flag that, when *True*, puts a > character in front of any line in the body that starts exactly as *From*, i.e. *From* followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such lines be mistaken for a Unix mailbox format envelope header separator (see [WHY THE CONTENT-LENGTH FORMAT IS BAD](#) for details). *mangle_from_* defaults to *True*, but you might want to set this to *False* if you are not writing Unix mailbox format files.

Optional *maxheaderlen* specifies the longest length for a non-continued header. When a header line is longer than *maxheaderlen* (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the *Header* class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by [RFC 2822](#).

The other public *Generator* methods are:

flatten (*msg*[, *unixfrom*])

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *Generator* instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded.

Optional *unixfrom* is a flag that forces the printing of the envelope header delimiter before the first [RFC 2822](#) header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to *False* to inhibit the printing of the envelope delimiter.

Note that for subparts, no envelope header is ever printed.

New in version 2.2.2.

clone (*fp*)

Return an independent clone of this *Generator* instance with the exact same options.

New in version 2.2.2.

write (*s*)

Write the string *s* to the underlying file object, i.e. *outfp* passed to *Generator*'s constructor. This provides just enough file-like API for *Generator* instances to be used in extended print statements.

As a convenience, see the methods *Message.as_string()* and *str(aMessage)*, a.k.a. *Message.__str__()*, which simplify the generation of a formatted string representation of a message object. For more detail, see *email.message*.

The *email.generator* module also provides a derived class, called *DecodedGenerator* which is like the *Generator* base class, except that non-*text* parts are substituted with a format string representing the part.

class *email.generator.DecodedGenerator* (*outfp*[, *mangle_from_*[, *maxheaderlen*[, *fmt*]])

This class, derived from *Generator* walks through all the subparts of a message. If the subpart is of main type

¹ This statement assumes that you use the appropriate setting for the *unixfrom* argument, and that you set *maxheaderlen*=0 (which will preserve whatever the input line lengths were). It is also not strictly true, since in many cases runs of whitespace in headers are collapsed into single blanks. The latter is a bug that will eventually be fixed.

text, then it prints the decoded payload of the subpart. Optional *_mangle_from_* and *maxheaderlen* are as with the *Generator* base class.

If the subpart is not of main type *text*, optional *fmt* is a format string that is used instead of the message payload. *fmt* is expanded with the following keywords, % (keyword) s format:

- *type* – Full MIME type of the non-*text* part
- *maintype* – Main MIME type of the non-*text* part
- *subtype* – Sub-MIME type of the non-*text* part
- *filename* – Filename of the non-*text* part
- *description* – Description associated with the non-*text* part
- *encoding* – Content transfer encoding of the non-*text* part

The default value for *fmt* is *None*, meaning

```
[Non-text (%(type)s) part of message omitted, filename %(filename)s]
```

New in version 2.2.2.

Changed in version 2.5: The previously deprecated method `__call__()` was removed.

18.1.4 `email.mime`: Creating email and MIME objects from scratch

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual *Message* objects by hand. In fact, you can also take an existing structure and add new *Message* objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating *Message* instances, adding attachments and all the appropriate headers manually. For MIME messages though, the *email* package provides some convenient subclasses to make things easier.

Here are the classes:

```
class email.mime.base.MIMEBase(_maintype, _subtype, **_params)
Module: email.mime.base
```

This is the base class for all the MIME-specific subclasses of *Message*. Ordinarily you won't create instances specifically of *MIMEBase*, although you could. *MIMEBase* is provided primarily as a convenient base class for more specific MIME-aware subclasses.

_maintype is the *Content-Type* major type (e.g. *text* or *image*), and *_subtype* is the *Content-Type* minor type (e.g. *plain* or *gif*). *_params* is a parameter key/value dictionary and is passed directly to *Message.add_header*.

The *MIMEBase* class always adds a *Content-Type* header (based on *_maintype*, *_subtype*, and *_params*), and a *MIME-Version* header (always set to 1.0).

```
class email.mime.nonmultipart.MIMENonMultipart
Module: email.mime.nonmultipart
```

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are not *multipart*. The primary purpose of this class is to prevent the use of the *attach()* method, which only makes sense for *multipart* messages. If *attach()* is called, a *MultipartConversionError* exception is raised.

New in version 2.2.2.

```
class email.mime.multipart.MIMEMultipart ([_subtype[, boundary[, _subparts[, _params ]]])
```

Module: email.mime.multipart

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are *multipart*. Optional *_subtype* defaults to *mixed*, but can be used to specify the subtype of the message. A *Content-Type* header of *multipart/_subtype* will be added to the message object. A *MIME-Version* header will also be added.

Optional *boundary* is the multipart boundary string. When *None* (the default), the boundary is calculated when needed (for example, when the message is serialized).

_subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the *Message.attach* method.

Additional parameters for the *Content-Type* header are taken from the keyword arguments, or passed into the *_params* argument, which is a keyword dictionary.

New in version 2.2.2.

```
class email.mime.application.MIMEApplication (_data[, _subtype[, _encoder[, **_params ]]])
```

Module: email.mime.application

A subclass of *MIMENonMultipart*, the *MIMEApplication* class is used to represent MIME message objects of major type *application*. *_data* is a string containing the raw byte data. Optional *_subtype* specifies the MIME subtype and defaults to *octet-stream*.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the *MIMEApplication* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

_params are passed straight through to the base class constructor.

New in version 2.5.

```
class email.mime.audio.MIMEAudio (_audiodata[, _subtype[, _encoder[, **_params ]]])
```

Module: email.mime.audio

A subclass of *MIMENonMultipart*, the *MIMEAudio* class is used to create MIME message objects of major type *audio*. *_audiodata* is a string containing the raw audio data. If this data can be decoded by the standard Python module *sndhdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the *_subtype* parameter. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the *MIMEAudio* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

_params are passed straight through to the base class constructor.

```
class email.mime.image.MIMEImage (_imagedata[, _subtype[, _encoder[, **_params ]]])
```

Module: email.mime.image

A subclass of *MIMENonMultipart*, the *MIMEImage* class is used to create MIME message objects of major type *image*. *_imagedata* is a string containing the raw image data. If this data can be decoded by the standard Python module *imghdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the *_subtype* parameter. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the `MIMEImage` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

`_params` are passed straight through to the `MIMEBase` constructor.

```
class email.mime.message.MIMEMessage(_msg[, _subtype])
```

Module: `email.mime.message`

A subclass of `MIMENonMultipart`, the `MIMEMessage` class is used to create MIME objects of main type *message*. `_msg` is used as the payload, and must be an instance of class `Message` (or a subclass thereof), otherwise a `TypeError` is raised.

Optional `_subtype` sets the subtype of the message; it defaults to `rfc822`.

```
class email.mime.text.MIMEText(_text[, _subtype[, _charset]])
```

Module: `email.mime.text`

A subclass of `MIMENonMultipart`, the `MIMEText` class is used to create MIME objects of major type *text*. `_text` is the string for the payload. `_subtype` is the minor type and defaults to `plain`. `_charset` is the character set of the text and is passed as a parameter to the `MIMENonMultipart` constructor; it defaults to `us-ascii`. If `_text` is unicode, it is encoded using the `output_charset` of `_charset`, otherwise it is used as-is.

Changed in version 2.4: The previously deprecated `_encoding` argument has been removed. Content Transfer Encoding now happens implicitly based on the `_charset` argument.

Unless the `_charset` parameter is explicitly set to `None`, the `MIMEText` object created will have both a *Content-Type* header with a `charset` parameter, and a *Content-Transfer-Encoding* header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can “reset” this behavior by deleting the *Content-Transfer-Encoding* header, after which a `set_payload` call will automatically encode the new payload (and add a new *Content-Transfer-Encoding* header).

18.1.5 email.header: Internationalized headers

RFC 2822 is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**. The `email` package supports these standards in its `email.header` and `email.charset` modules.

If you want to include non-ASCII characters in your email headers, say in the *Subject* or *To* fields, you should use the `Header` class and assign the field in the `Message` object to an instance of `Header` instead of using a string for the header value. Import the `Header` class from the `email.header` module. For example:

```
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> print msg.as_string()
Subject: =?iso-8859-1?q?p=F6stal?=>>>
```

Notice here how we wanted the *Subject* field to contain a non-ASCII character? We did this by creating a *Header* instance and passing in the character set that the byte string was encoded in. When the subsequent *Message* instance was flattened, the *Subject* field was properly **RFC 2047** encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

New in version 2.2.2.

Here is the *Header* class description:

```
class email.header.Header ([s[, charset[, maxlinelen[, header_name[, continuation_ws[, errors]]]]])
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional *s* is the initial header value. If *None* (the default), the initial header value is not set. You can later append to the header with *append()* method calls. *s* may be a byte string or a Unicode string, but see the *append()* documentation for semantics.

Optional *charset* serves two purposes: it has the same meaning as the *charset* argument to the *append()* method. It also sets the default character set for all subsequent *append()* calls that omit the *charset* argument. If *charset* is not provided in the constructor (the default), the *us-ascii* character set is used both as *s*'s initial charset and as the default for subsequent *append()* calls.

The maximum line length can be specified explicitly via *maxlinelen*. For splitting the first line to a shorter value (to account for the field header which isn't included in *s*, e.g. *Subject*) pass in the name of the field in *header_name*. The default *maxlinelen* is 76, and the default value for *header_name* is *None*, meaning it is not taken into account for the first line of a long, split header.

Optional *continuation_ws* must be **RFC 2822**-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. *continuation_ws* defaults to a single space character (" ").

Optional *errors* is passed straight through to the *append()* method.

```
append (s[, charset[, errors]]])
```

Append the string *s* to the MIME header.

Optional *charset*, if given, should be a *Charset* instance (see *email.charset*) or the name of a character set, which will be converted to a *Charset* instance. A value of *None* (the default) means that the *charset* given in the constructor is used.

s may be a byte string or a Unicode string. If it is a byte string (i.e. *isinstance(s, str)* is true), then *charset* is the encoding of that byte string, and a *UnicodeError* will be raised if the string cannot be decoded with that character set.

If *s* is a Unicode string, then *charset* is a hint specifying the character set of the characters in the string. In this case, when producing an **RFC 2822**-compliant header using **RFC 2047** rules, the Unicode string will be encoded using the following charsets in order: *us-ascii*, the *charset* hint, *utf-8*. The first character set to not provoke a *UnicodeError* is used.

Optional *errors* is passed through to any *unicode()* or *unicode.encode()* call, and defaults to "strict".

```
encode ([splitchars])
```

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings. Optional *splitchars* is a string containing characters to split long ASCII lines on, in rough support of **RFC 2822**'s *highest level syntactic breaks*. This doesn't affect **RFC 2047** encoded lines.

The *Header* class also provides a number of methods to support standard operators and built-in functions.

```
__str__ ()
```

A synonym for *Header.encode()*. Useful for *str(aHeader)*.

`__unicode__()`

A helper for the built-in `unicode()` function. Returns the header as a Unicode string.

`__eq__(other)`

This method allows you to compare two `Header` instances for equality.

`__ne__(other)`

This method allows you to compare two `Header` instances for inequality.

The `email.header` module also provides the following convenient functions.

`email.header.decode_header(header)`

Decode a message header value without converting the character set. The header value is in `header`.

This function returns a list of `(decoded_string, charset)` pairs containing each of the decoded parts of the header. `charset` is `None` for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here's an example:

```
>>> from email.header import decode_header
>>> decode_header('=?iso-8859-1?q?p=F6stal?')
[('p\xf6stal', 'iso-8859-1')]
```

`email.header.make_header(decoded_seq[, maxlinelen[, header_name[, continuation_ws]]])`

Create a `Header` instance from a sequence of pairs as returned by `decode_header()`.

`decode_header()` takes a header value string and returns a sequence of pairs of the format `(decoded_string, charset)` where `charset` is the name of the character set.

This function takes one of those sequence of pairs and returns a `Header` instance. Optional `maxlinelen`, `header_name`, and `continuation_ws` are as in the `Header` constructor.

18.1.6 email.charset: Representing character sets

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

New in version 2.2.2.

class `email.charset.Charset([input_charset])`

Map character sets to their email properties.

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional `input_charset` is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if `input_charset` is `iso-8859-1`, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If `input_charset` is `euc-jp`, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the `euc-jp` character set to the `iso-2022-jp` character set.

Charset instances have the following data attributes:

input_charset

The initial character set specified. Common aliases are converted to their *official* email names (e.g. `latin_1` is converted to `iso-8859-1`). Defaults to 7-bit `us-ascii`.

header_encoding

If the character set must be encoded before it can be used in an email header, this attribute will be set to `Charset.QP` (for quoted-printable), `Charset.BASE64` (for base64 encoding), or `Charset.SHORTEST` for the shortest of QP or BASE64 encoding. Otherwise, it will be `None`.

body_encoding

Same as *header_encoding*, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. `Charset.SHORTEST` is not allowed for *body_encoding*.

output_charset

Some character sets must be converted before they can be used in email headers or bodies. If the *input_charset* is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be `None`.

input_codec

The name of the Python codec used to convert the *input_charset* to Unicode. If no conversion codec is necessary, this attribute will be `None`.

output_codec

The name of the Python codec used to convert Unicode to the *output_charset*. If no conversion codec is necessary, this attribute will have the same value as the *input_codec*.

Charset instances also have the following methods:

get_body_encoding()

Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the *Message* object being encoded. The function should then set the *Content-Transfer-Encoding* header itself to whatever is appropriate.

Returns the string `quoted-printable` if *body_encoding* is `QP`, returns the string `base64` if *body_encoding* is `BASE64`, and returns the string `7bit` otherwise.

convert(s)

Convert the string *s* from the *input_codec* to the *output_codec*.

to_splittable(s)

Convert a possibly multibyte string to a safely splittable format. *s* is the string to split.

Uses the *input_codec* to try and convert the string to Unicode, so it can be safely split on character boundaries (even for multibyte characters).

Returns the string as-is if it isn't known how to convert *s* to Unicode with the *input_charset*.

Characters that could not be converted to Unicode will be replaced with the Unicode replacement character `'U+FFFD'`.

from_splittable(ustr[, to_output])

Convert a splittable string back into an encoded string. *ustr* is a Unicode string to “unsplit”.

This method uses the proper codec to try and convert the string from Unicode back into an encoded format. Return the string as-is if it is not Unicode, or if it could not be converted from Unicode.

Characters that could not be converted from Unicode will be replaced with an appropriate character (usually `'?'`).

If *to_output* is `True` (the default), uses *output_codec* to convert to an encoded format. If *to_output* is `False`, it uses *input_codec*.

get_output_charset ()

Return the output character set.

This is the *output_charset* attribute if that is not `None`, otherwise it is *input_charset*.

encoded_header_len ()

Return the length of the encoded header string, properly calculating for quoted-printable or base64 encoding.

header_encode (s[, convert])

Header-encode the string *s*.

If *convert* is `True`, the string will be converted from the input charset to the output charset automatically. This is not useful for multibyte character sets, which have line length issues (multibyte characters must be split on a character, not a byte boundary); use the higher-level *Header* class to deal with these issues (see *email.header*). *convert* defaults to `False`.

The type of encoding (base64 or quoted-printable) will be based on the *header_encoding* attribute.

body_encode (s[, convert])

Body-encode the string *s*.

If *convert* is `True` (the default), the string will be converted from the input charset to output charset automatically. Unlike *header_encode()*, there are no issues with byte boundaries and multibyte charsets in email bodies, so this is usually pretty safe.

The type of encoding (base64 or quoted-printable) will be based on the *body_encoding* attribute.

The *Charset* class also provides a number of methods to support standard operations and built-in functions.

__str__ ()

Returns *input_charset* as a string coerced to lower case. *__repr__()* is an alias for *__str__()*.

__eq__ (other)

This method allows you to compare two *Charset* instances for equality.

__ne__ (other)

This method allows you to compare two *Charset* instances for inequality.

The *email.charset* module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

`email.charset.add_charset(charset[, header_enc[, body_enc[, output_charset]])`

Add character properties to the global registry.

charset is the input character set, and must be the canonical name of a character set.

Optional *header_enc* and *body_enc* is either *Charset.QP* for quoted-printable, *Charset.BASE64* for base64 encoding, *Charset.SHORTEST* for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. *SHORTEST* is only valid for *header_enc*. The default is `None` for no encoding.

Optional *output_charset* is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method *Charset.convert()* is called. The default is to output in the same character set as the input.

Both *input_charset* and *output_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use *add_codec()* to add codecs the module does not know about. See the *codecs* module's documentation for more information.

The global character set registry is kept in the module global dictionary *CHARSETS*.

`email.charset.add_alias(alias, canonical)`

Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

`email.charset.add_codec(charset, codecname)`

Add a codec that map characters in the given character set to and from Unicode.

charset is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `unicode()` built-in, or to the `encode()` method of a Unicode string.

18.1.7 email.encoders: Encoders

When creating *Message* objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for *image/** and *text/** type messages containing binary data.

The *email* package provides some convenient encodings in its *encoders* module. These encoders are actually used by the *MIMEAudio* and *MIMEImage* class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the *Content-Transfer-Encoding* header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a *TypeError* if passed a message whose type is multipart.

Here are the encoding functions provided:

`email.encoders.encode_quopri(msg)`

Encodes the payload into quoted-printable form and sets the *Content-Transfer-Encoding* header to *quoted-printable*¹. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

`email.encoders.encode_base64(msg)`

Encodes the payload into base64 form and sets the *Content-Transfer-Encoding* header to *base64*. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

`email.encoders.encode_7or8bit(msg)`

This doesn't actually modify the message's payload, but it does set the *Content-Transfer-Encoding* header to either *7bit* or *8bit* as appropriate, based on the payload data.

`email.encoders.encode_noop(msg)`

This does nothing; it doesn't even set the *Content-Transfer-Encoding* header.

18.1.8 email.errors: Exception and Defect classes

The following exception classes are defined in the *email.errors* module:

exception `email.errors.MessageError`

This is the base class for all exceptions that the *email* package can raise. It is derived from the standard *Exception* class and defines no additional methods.

exception `email.errors.MessageParseError`

This is the base class for exceptions raised by the *Parser* class. It is derived from *MessageError*.

¹ Note that encoding with `encode_quopri()` also encodes all tabs and space characters in the data.

exception `email.errors.HeaderParseError`

Raised under some error conditions when parsing the **RFC 2822** headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

Situations where it can be raised include finding an envelope header after the first **RFC 2822** header of the message, finding a continuation line before the first **RFC 2822** header is found, or finding a line in the headers which is neither a header or a continuation line.

exception `email.errors.BoundaryError`

Raised under some error conditions when parsing the **RFC 2822** headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

Situations where it can be raised include not being able to find the starting or terminating boundary in a `multipart/*` message when strict parsing is used.

exception `email.errors.MultipartConversionError`

Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message's `Content-Type` main type is not either `multipart` or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here's the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a `multipart/alternative` had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`, but this class is *not* an exception!

New in version 2.4: All the defect classes were added.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no *boundary* parameter.
- `StartBoundaryNotFoundDefect` – The start boundary claimed in the *Content-Type* header was never found.
- `FirstHeaderLineIsContinuationDefect` – The message had a continuation line as its first header line.
- `MisplacedEnvelopeHeaderDefect` – A “Unix From” header was found in the middle of a header block.
- `MalformedHeaderDefect` – A header was found that was missing a colon, or was otherwise malformed.
- `MultipartInvariantViolationDefect` – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return false even though its content type claims to be *multipart*.

18.1.9 email.utils: Miscellaneous utilities

There are several useful utilities provided in the `email.utils` module:

`email.utils.quote(str)`

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

`email.utils.unquote(str)`

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

`email.utils.parseaddr(address)`

Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of ('', '') is returned.

`email.utils.formataddr(pair)`

The inverse of `parseaddr()`, this takes a 2-tuple of the form (*realname*, *email_address*) and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

`email.utils.getaddresses(fieldvalues)`

This method returns a list of 2-tuples of the form returned by `parseaddr()`. *fieldvalues* is a sequence of header field values as might be returned by `Message.get_all`. Here's a simple example that gets all the recipients of a message:

```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

`email.utils.parsedate(date)`

Attempts to parse a date according to the rules in [RFC 2822](#). However, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. *date* is a string containing an [RFC 2822](#) date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise None will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`email.utils.parsedate_tz(date)`

Performs the same function as `parsedate()`, but returns either None or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time)¹. If the input string has no timezone, the last element of the tuple returned is None. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`email.utils.mktime_tz(tuple)`

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is None, assume local time.

`email.utils.formatdate([timeval[, localtime][, usegmt]])`

Returns a date string as per [RFC 2822](#), e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional *timeval* if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.

Optional *localtime* is a flag that when True, interprets *timeval*, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is False meaning UTC is used.

Optional *usegmt* is a flag that when True, outputs a date string with the timezone as an ascii string GMT, rather than a numeric -0000. This is needed for some protocols (such as HTTP). This only applies when *localtime* is False. The default is False.

New in version 2.4.

¹ Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows [RFC 2822](#).

`email.utils.make_msgid([idstring])`

Returns a string suitable for an **RFC 2822**-compliant *Message-ID* header. Optional *idstring* if given, is a string used to strengthen the uniqueness of the message id.

`email.utils.decode_rfc2231(s)`

Decode the string *s* according to **RFC 2231**.

`email.utils.encode_rfc2231(s[, charset[, language]])`

Encode the string *s* according to **RFC 2231**. Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, *s* is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

`email.utils.collapse_rfc2231_value(value[, errors[, fallback_charset]])`

When a header parameter is encoded in **RFC 2231** format, *Message.get_param* may return a 3-tuple containing the character set, language, and value. *collapse_rfc2231_value()* turns this into a unicode string. Optional *errors* is passed to the *errors* argument of the built-in *unicode()* function; it defaults to *replace*. Optional *fallback_charset* specifies the character set to use if the one in the **RFC 2231** header is not known by Python; it defaults to *us-ascii*.

For convenience, if the *value* passed to *collapse_rfc2231_value()* is not a tuple, it should be a string and it is returned unquoted.

`email.utils.decode_params(params)`

Decode parameters list according to **RFC 2231**. *params* is a sequence of 2-tuples containing elements of the form (content-type, string-value).

Changed in version 2.4: The *dump_address_pair()* function has been removed; use *formataddr()* instead.

Changed in version 2.4: The *decode()* function has been removed; use the *Header.decode_header* method instead.

Changed in version 2.4: The *encode()* function has been removed; use the *Header.encode* method instead.

18.1.10 email.iterators: Iterators

Iterating over a message object tree is fairly easy with the *Message.walk* method. The *email.iterators* module provides some useful higher level iterations over message object trees.

`email.iterators.body_line_iterator(msg[, decode])`

This iterates over all the payloads in all the subparts of *msg*, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn't a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using *readline()*, skipping over all the intervening headers.

Optional *decode* is passed through to *Message.get_payload*.

`email.iterators.typed_subpart_iterator(msg[, maintype[, subtype]])`

This iterates over all the subparts of *msg*, returning only those subparts that match the MIME type specified by *maintype* and *subtype*.

Note that *subtype* is optional; if omitted, then subpart MIME type matching is done only with the main type. *maintype* is optional too; it defaults to *text*.

Thus, by default *typed_subpart_iterator()* returns each subpart that has a MIME type of *text/**.

The following function has been added as a useful debugging tool. It should *not* be considered part of the supported public interface for the package.

`email.iterators._structure(msg[, fp[, level]])`

Prints an indented representation of the content types of the message object structure. For example:

```

>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
  text/plain
  text/plain
  multipart/digest
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
  text/plain

```

Optional *fp* is a file-like object to print the output to. It must be suitable for Python's extended print statement. *level* is used internally.

18.1.11 email: Examples

Here are a few examples of how to use the *email* package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message:

```

# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.mime.text import MIMEText

# Open a plain text file for reading. For this example, assume that
# the text file contains only ASCII characters.
fp = open(textfile, 'rb')
# Create a text/plain message
msg = MIMEText(fp.read())
fp.close()

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server, but don't include the
# envelope header.
s = smtplib.SMTP('localhost')
s.sendmail(me, [you], msg.as_string())
s.quit()

```

And parsing RFC822 headers can easily be done by the *parse(filename)* or *parsestr(message_as_string)* methods of the *Parser()* class:

```
# Import the email modules we'll need
from email.parser import Parser

# If the e-mail headers are in a file, uncomment this line:
#headers = Parser().parse(open(messagefile, 'r'))

# Or for parsing headers in a string, use:
headers = Parser().parsestr('From: <user@example.com>\n'
    'To: <someone_else@example.com>\n'
    'Subject: Test message\n'
    '\n'
    'Body would go here\n')

# Now the header items can be accessed as a dictionary:
print 'To: %s' % headers['to']
print 'From: %s' % headers['from']
print 'Subject: %s' % headers['subject']
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```
# Import smtplib for the actual sending function
import smtplib

# Here are the email package modules we'll need
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart

COMMASPACE = ', '

# Create the container (outer) email message.
msg = MIMEMultipart()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = COMMASPACE.join(family)
msg.preamble = 'Our family reunion'

# Assume we know that the image files are all in PNG format
for file in pngfiles:
    # Open the files in binary mode. Let the MIMEImage class automatically
    # guess the specific image type.
    fp = open(file, 'rb')
    img = MIMEImage(fp.read())
    fp.close()
    msg.attach(img)

# Send the email via our own SMTP server.
s = smtplib.SMTP('localhost')
s.sendmail(me, family, msg.as_string())
s.quit()
```

Here's an example of how to send the entire contents of a directory as an email message:¹

¹ Thanks to Matthew Dixon Cowles for the original inspiration and examples.

```
#!/usr/bin/env python

"""Send the contents of a directory as a MIME message."""

import os
import sys
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from optparse import OptionParser

from email import encoders
from email.message import Message
from email.mime.audio import MIMEAudio
from email.mime.base import MIMEBase
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

COMMASPACE = ', '

def main():
    parser = OptionParser(usage="""\
Send the contents of a directory as a MIME message.

Usage: %prog [options]

Unless the -o option is given, the email is sent by forwarding to your local
SMTP server, which then does the normal delivery process. Your local machine
must be running an SMTP server.
""")
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Mail the contents of the specified directory,
otherwise use the current directory. Only the regular
files in the directory are sent, and we don't recurse to
subdirectories.""")
    parser.add_option('-o', '--output',
                      type='string', action='store', metavar='FILE',
                      help="""Print the composed message to FILE instead of
sending the message to the SMTP server.""")
    parser.add_option('-s', '--sender',
                      type='string', action='store', metavar='SENDER',
                      help='The value of the From: header (required)')
    parser.add_option('-r', '--recipient',
                      type='string', action='append', metavar='RECIPIENT',
                      default=[], dest='recipients',
                      help='A To: header value (at least one required)')
    opts, args = parser.parse_args()
    if not opts.sender or not opts.recipients:
        parser.print_help()
        sys.exit(1)
    directory = opts.directory
    if not directory:
        directory = '.'
```

(continues on next page)

(continued from previous page)

```

# Create the enclosing (outer) message
outer = MIMEMultipart()
outer['Subject'] = 'Contents of directory %s' % os.path.abspath(directory)
outer['To'] = COMMASPACE.join(opts.recipients)
outer['From'] = opts.sender
outer.preamble = 'You will not see this in a MIME-aware mail reader.\n'

for filename in os.listdir(directory):
    path = os.path.join(directory, filename)
    if not os.path.isfile(path):
        continue
    # Guess the content type based on the file's extension. Encoding
    # will be ignored, although we should check for simple things like
    # gzip'd or compressed files.
    ctype, encoding = mimetypes.guess_type(path)
    if ctype is None or encoding is not None:
        # No guess could be made, or the file is encoded (compressed), so
        # use a generic bag-of-bits type.
        ctype = 'application/octet-stream'
    maintype, subtype = ctype.split('/', 1)
    if maintype == 'text':
        fp = open(path)
        # Note: we should handle calculating the charset
        msg = MIMEText(fp.read(), _subtype=subtype)
        fp.close()
    elif maintype == 'image':
        fp = open(path, 'rb')
        msg = MIMEImage(fp.read(), _subtype=subtype)
        fp.close()
    elif maintype == 'audio':
        fp = open(path, 'rb')
        msg = MIMEAudio(fp.read(), _subtype=subtype)
        fp.close()
    else:
        fp = open(path, 'rb')
        msg = MIMEBase(maintype, subtype)
        msg.set_payload(fp.read())
        fp.close()
        # Encode the payload using Base64
        encoders.encode_base64(msg)
    # Set the filename parameter
    msg.add_header('Content-Disposition', 'attachment', filename=filename)
    outer.attach(msg)

# Now send or store the message
composed = outer.as_string()
if opts.output:
    fp = open(opts.output, 'w')
    fp.write(composed)
    fp.close()
else:
    s = smtplib.SMTP('localhost')
    s.sendmail(opts.sender, opts.recipients, composed)
    s.quit()

if __name__ == '__main__':
    main()

```

Here's an example of how to unpack a MIME message like the one above, into a directory of files:

```
#!/usr/bin/env python

"""Unpack a MIME message into a directory of files."""

import os
import sys
import email
import errno
import mimetypes

from optparse import OptionParser

def main():
    parser = OptionParser(usage="""\
Unpack a MIME message into a directory of files.

Usage: %prog [options] msgfile
""")
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Unpack the MIME message into the named
                      directory, which will be created if it doesn't already
                      exist.""")
    opts, args = parser.parse_args()
    if not opts.directory:
        parser.print_help()
        sys.exit(1)

    try:
        msgfile = args[0]
    except IndexError:
        parser.print_help()
        sys.exit(1)

    try:
        os.mkdir(opts.directory)
    except OSError as e:
        # Ignore directory exists error
        if e.errno != errno.EEXIST:
            raise

    fp = open(msgfile)
    msg = email.message_from_file(fp)
    fp.close()

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given filename so that an
        # email message can't be used to overwrite important files
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_content_type())
```

(continues on next page)

(continued from previous page)

```

        if not ext:
            # Use a generic bag-of-bits extension
            ext = '.bin'
            filename = 'part-%03d%s' % (counter, ext)
            counter += 1
            fp = open(os.path.join(opts.directory, filename), 'wb')
            fp.write(part.get_payload(decode=True))
            fp.close()

if __name__ == '__main__':
    main()

```

Here's an example of how to create an HTML message with an alternative plain text version:²

```

#!/usr/bin/env python

import smtplib

from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

# me == my email address
# you == recipient's email address
me = "my@email.com"
you = "your@email.com"

# Create message container - the correct MIME type is multipart/alternative.
msg = MIMEMultipart('alternative')
msg['Subject'] = "Link"
msg['From'] = me
msg['To'] = you

# Create the body of the message (a plain-text and an HTML version).
text = "Hi!\nHow are you?\nHere is the link you wanted:\nhttps://www.python.org"
html = """\
<html>
  <head></head>
  <body>
    <p>Hi!<br>
      How are you?<br>
      Here is the <a href="https://www.python.org">link</a> you wanted.
    </p>
  </body>
</html>
"""

# Record the MIME types of both parts - text/plain and text/html.
part1 = MIMEText(text, 'plain')
part2 = MIMEText(html, 'html')

# Attach parts into message container.
# According to RFC 2046, the last part of a multipart message, in this case
# the HTML message, is best and preferred.
msg.attach(part1)

```

(continues on next page)

² Contributed by Martin Matejek.

(continued from previous page)

```

msg.attach(part2)

# Send the message via local SMTP server.
s = smtplib.SMTP('localhost')
# sendmail function takes 3 arguments: sender's address, recipient's address
# and message to send - here it is sent as one string.
s.sendmail(me, you, msg.as_string())
s.quit()

```

18.1.12 Package History

This table describes the release history of the email package, corresponding to the version of Python that the package was released with. For purposes of this document, when you see a note about change or added versions, these refer to the Python version the change was made in, *not* the email package version. This table also describes the Python compatibility of each version of the package.

| email version | distributed with | compatible with |
|---------------|------------------------------|----------------------------|
| 1.x | Python 2.2.0 to Python 2.2.1 | <i>no longer supported</i> |
| 2.5 | Python 2.2.2+ and Python 2.3 | Python 2.1 to 2.5 |
| 3.0 | Python 2.4 | Python 2.3 to 2.5 |
| 4.0 | Python 2.5 | Python 2.3 to 2.5 |

Here are the major differences between *email* version 4 and version 3:

- All modules have been renamed according to **PEP 8** standards. For example, the version 3 module `email.Message` was renamed to `email.message` in version 4.
- A new subpackage `email.mime` was added and all the version 3 `email.MIME*` modules were renamed and situated into the `email.mime` subpackage. For example, the version 3 module `email.MIMEText` was renamed to `email.mime.text`.

Note that the version 3 names will continue to work until Python 2.6.

- The `email.mime.application` module was added, which contains the `MIMEApplication` class.
- Methods that were deprecated in version 3 have been removed. These include `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, `Message.get_subtype()`.
- Fixes have been added for **RFC 2231** support which can change some of the return types for `Message.get_param` and friends. Under some circumstances, values which used to return a 3-tuple now return simple strings (specifically, if all extended parameter segments were unencoded, there is no language and charset designation expected, so the return type is now a simple string). Also, %-decoding used to be done for both encoded and unencoded segments; this decoding is now done only for encoded segments.

Here are the major differences between *email* version 3 and version 2:

- The `FeedParser` class was introduced, and the `Parser` class was implemented in terms of the `FeedParser`. All parsing therefore is non-strict, and parsing will make a best effort never to raise an exception. Problems found while parsing messages are stored in the message's `defect` attribute.

- All aspects of the API which raised *DeprecationWarnings* in version 2 have been removed. These include the `_encoder` argument to the *MIMEText* constructor, the `Message.add_payload()` method, the `Utils.dump_address_pair()` function, and the functions `Utils.decode()` and `Utils.encode()`.
- New *DeprecationWarnings* have been added to: `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, `Message.get_subtype()`, and the *strict* argument to the *Parser* class. These are expected to be removed in future versions.
- Support for Pythons earlier than 2.3 has been removed.

Here are the differences between *email* version 2 and version 1:

- The `email.Header` and `email.Charset` modules have been added.
- The pickle format for *Message* instances has changed. Since this was never (and still isn't) formally defined, this isn't considered a backward incompatibility. However if your application pickles and unpickles *Message* instances, be aware that in *email* version 2, *Message* instances now have private variables `_charset` and `_default_type`.
- Several methods in the *Message* class have been deprecated, or their signatures changed. Also, many new methods have been added. See the documentation for the *Message* class for details. The changes should be completely backward compatible.
- The object structure has changed in the face of *message/rfc822* content types. In *email* version 1, such a type would be represented by a scalar payload, i.e. the container message's `is_multipart()` returned false, `get_payload()` was not a list object, but a single *Message* instance.

This structure was inconsistent with the rest of the package, so the object representation for *message/rfc822* content types was changed. In *email* version 2, the container *does* return True from `is_multipart()`, and `get_payload()` returns a list containing a single *Message* item.

Note that this is one place that backward compatibility could not be completely maintained. However, if you're already testing the return type of `get_payload()`, you should be fine. You just need to make sure your code doesn't do a `set_payload()` with a *Message* instance on a container with a content type of *message/rfc822*.

- The *Parser* constructor's *strict* argument was added, and its `parse()` and `parsestr()` methods grew a *headersonly* argument. The *strict* flag was also added to functions `email.message_from_file()` and `email.message_from_string()`.
- `Generator.__call__()` is deprecated; use *Generator.flatten* instead. The *Generator* class has also grown the `clone()` method.
- The *DecodedGenerator* class in the *email.generator* module was added.
- The intermediate base classes *MIMENonMultipart* and *MIMEMultipart* have been added, and interposed in the class hierarchy for most of the other MIME-related derived classes.
- The `_encoder` argument to the *MIMEText* constructor has been deprecated. Encoding now happens implicitly based on the `_charset` argument.
- The following functions in the `email.Utils` module have been deprecated: `dump_address_pairs()`, `decode()`, and `encode()`. The following functions have been added to the module: `make_msgid()`, `decode_rfc2231()`, `encode_rfc2231()`, and `decode_params()`.
- The non-public function `email.Iterators._structure()` was added.

18.1.13 Differences from *mimelib*

The *email* package was originally prototyped as a separate library called *mimelib*. Changes have been made so that method names are more consistent, and some methods or modules have either been added or removed. The semantics

of some of the methods have also changed. For the most part, any functionality available in `mimelib` is still available in the `email` package, albeit often in a different way. Backward compatibility between the `mimelib` package and the `email` package was not a priority.

Here is a brief description of the differences between the `mimelib` and the `email` packages, along with hints on how to port your applications.

Of course, the most visible difference between the two packages is that the package name has been changed to `email`. In addition, the top-level package has the following differences:

- `messageFromString()` has been renamed to `message_from_string()`.
- `messageFromFile()` has been renamed to `message_from_file()`.

The `Message` class has the following differences:

- The method `asString()` was renamed to `as_string()`.
- The method `ismultipart()` was renamed to `is_multipart()`.
- The `get_payload()` method has grown a `decode` optional argument.
- The method `getall()` was renamed to `get_all()`.
- The method `addheader()` was renamed to `add_header()`.
- The method `gettype()` was renamed to `get_type()`.
- The method `getmaintype()` was renamed to `get_main_type()`.
- The method `getsubtype()` was renamed to `get_subtype()`.
- The method `getparams()` was renamed to `get_params()`. Also, whereas `getparams()` returned a list of strings, `get_params()` returns a list of 2-tuples, effectively the key/value pairs of the parameters, split on the '=' sign.
- The method `getparam()` was renamed to `get_param()`.
- The method `getcharsets()` was renamed to `get_charsets()`.
- The method `getfilename()` was renamed to `get_filename()`.
- The method `getboundary()` was renamed to `get_boundary()`.
- The method `setboundary()` was renamed to `set_boundary()`.
- The method `getdecodedpayload()` was removed. To get similar functionality, pass the value 1 to the `decode` flag of the `get_payload()` method.
- The method `getpayloadastext()` was removed. Similar functionality is supported by the `DecodedGenerator` class in the `email.generator` module.
- The method `getbodyastext()` was removed. You can get similar functionality by creating an iterator with `typed_subpart_iterator()` in the `email.iterators` module.

The `Parser` class has no differences in its public interface. It does have some additional smarts to recognize `message/delivery-status` type messages, which it represents as a `Message` instance containing separate `Message` subparts for each header block in the delivery status notification¹.

The `Generator` class has no differences in its public interface. There is a new class in the `email.generator` module though, called `DecodedGenerator` which provides most of the functionality previously available in the `Message.getpayloadastext()` method.

The following modules and classes have been changed:

¹ Delivery Status Notifications (DSN) are defined in [RFC 1894](#).

- The `MIMEBase` class constructor arguments `_major` and `_minor` have changed to `_maintype` and `_subtype` respectively.
- The `Image` class/module has been renamed to `MIMEImage`. The `_minor` argument has been renamed to `_subtype`.
- The `Text` class/module has been renamed to `MIMEText`. The `_minor` argument has been renamed to `_subtype`.
- The `MessageRFC822` class/module has been renamed to `MIMEMessage`. Note that an earlier version of `mimelib` called this class/module `RFC822`, but that clashed with the Python standard library module `rfc822` on some case-insensitive file systems.

Also, the `MIMEMessage` class now represents any kind of MIME message with main type `message`. It takes an optional argument `_subtype` which is used to set the MIME subtype. `_subtype` defaults to `rfc822`.

`mimelib` provided some utility functions in its `address` and `date` modules. All of these functions have been moved to the `email.utils` module.

The `MsgReader` class/module has been removed. Its functionality is most closely supported in the `body_line_iterator()` function in the `email.iterators` module.

18.2 json — JSON encoder and decoder

New in version 2.6.

JSON (JavaScript Object Notation), specified by [RFC 7159](#) (which obsoletes [RFC 4627](#)) and by [ECMA-404](#), is a lightweight data interchange format inspired by JavaScript object literal syntax (although it is not a strict subset of JavaScript¹).

`json` exposes an API familiar to users of the standard library `marshal` and `pickle` modules.

Encoding basic Python object hierarchies:

```
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}])
'["foo", {"bar": ["baz", null, 1.0, 2]}]'
>>> print json.dumps("\"foo\\bar\"")
\"foo\\bar\"
>>> print json.dumps(u'\\u1234')
\"u1234\"
>>> print json.dumps('\\\\')
\"\\\"
>>> print json.dumps({'c': 0, 'b': 0, 'a': 0}, sort_keys=True)
{"a": 0, "b": 0, "c": 0}
